| Outline clinically important drug interactions with the autonomic nervous system                                                                                                                                                                                                                                                                                    | 49 |
| Describe the physiological and pharmacological basis of antiarrhythmic therapy including classification based on electro-physiological activity and mechanism of action                                                                                                                                                                                             | 49 |
| Describe the pharmacology of antiarrhythmic agents and their clinical applications including the following agents: lignocaine, flecainide, beta blockers, amiodarone, sotalol, ibutilide, calcium antagonists, digoxin, adenosine and magnesium                                                                                                                     | 49 |
| Sodium channel blockers                                                                                                                                                                                                                                                                                                                                             | 51 |
| Calcium channel blockers                                                                                                                                                                                                                                                                                                                                            | 52 |
| Other antiarrhythmics                                                                                                                                                                                                                                                                                                                                               | 54 |
| Describe the pharmacology of anti-hypertensive agents and their clinical application, including the following agents: clonidine, alpha-methyl dopa, alpha and beta blockers, nitric oxide, sodium nitroprusside and glyceryl trinitrate, calcium antagonists, ACE inhibitors and angiotensin receptor antagonists, hydralazine and the potassium channel activators | 56 |
| Centrally acting antihypertensives                                                                                                                                                                                                                                                                                                                                  | 57 |
| Direct vasodilator antihypertensives                                                                                                                                                                                                                                                                                                                                | 58 |
| K channel activators                                                                                                                                                                                                                                                                                                                                                | 59 |
| ACEI/ ARBs                                                                                                                                                                                                                                                                                                                                                          | 60 |
| Management of hypertensive crisis: PAST QUESTION                                                                                                                                                                                                                                                                                                                    | 61 |
| Describe the mechanism and treatment of the toxicity of sodium nitroprusside: PAST QUESTION                                                                                                                                                                                                                                                                         | 61 |
| Describe the pharmacology of drugs used to manage myocardial ischaemia/infarction, including: nitrates, beta blockers, calcium antagonists, anti-platelet agents, anticoagulants and fibrinolytic agents                                                                                                                                                            | 62 |
| Describe the pharmacology of drugs used to manage acute or chronic cardiac failure, including: sympathomimetics, phosphodiesterase inhibitors, digoxin, diuretics, ACE inhibitors, nitrates and beta blockers                                                                                                                                                       | 62 |

## Anatomy of the major arteries and veins

### *Anatomy of the heart, the pericardium and valves – FROM CICM*

#### Anatomy of the heart

- heart located in thorax, enclosed within fibrous sac (pericardium)
- 3 tissue layers:
  - o Epicardium: outer connective tissue layer
  - o Myocardium: cardiac muscle
  - o Endocardium: epithelial cells; line inner surface
- divided into R + L sides
  - o each consisting of atrium + ventricle
  - o separated by interatrial + interventricular septae
- 4 chambers: RA, RV, LA, LV
  - o RA: receives deoxygenated blood from SVC + IVC; tricuspid valve
  - o RV: crescent shape in transverse plane; triangular in longitudinal plane; pulmonary valve
  - o LA: oxygenated blood returns from lungs through 4 pulmonary veins to the LA; mitral valve
  - o LV: circular transverse section, conical longitudinal section; aortic valve
- Myocardium
  - o “functional syncytium” – cardiac muscle = electrically, chemically, mechanically coupled together
  - o Arranged in networks of striated cardiac muscle cells joined together by intercalated discs
  - o Intercalated discs contain 3 different types of cell-cell interaction:
    - 1. Gap junctions: permit direct passage of intracellular ions + molecules from one cell to another → allows direct electrical spread of AP from cell to cell
    - 2. fascia adherens: anchor actin filaments within sarcomere to the cell membrane
    - 3. macular adherens (desmosomes): anchor cardiac cells to one another
- Fibrous skeleton
  - o Dense collagen; forms 4 fibrous rings (surrounds valves); R and L fibrous trigones; and interatrial and interventricular septa
  - o Maintains valvular patency and prevents distension
  - o attach valvular leaflets and cusps
  - o attach myocardium
  - o provide electrical insulation, therefore separating atrial and ventricular impulses, surrounding and providing passage for the AV bundle

#### Pericardium

- Double walled sack:
  - o external fibrous layer: fused with...
    - anteriorly: tunica adventitia of great vessels + sternum
    - inferiorly: central tendon of diaphragm
    - posteriorly: loose connective tissue
  - o Serosus parietal layer: reflects onto heart + great vessels as visceral pericardium

#### Cardiac valves

- consist of thin flaps of flexible, tough, endothelium-covered fibrous tissue that are firmly attached to the base of the fibrous valve rings
- movement of valve leaflets is essentially passive
- orientation of the valves is responsible for the unidirectional flow of blood through the heart
- 2 types of valves: atrioventricular + semilunar
  - o Atrioventricular valves
    - Tricuspid: between RA and RV; 3 cusps
    - Mitral: between LA and LV; 2 cusps
    - Chordae tendinae arise from papillary muscles → attach to valves → prevent valves from everting during ventricular systole
  - o Semilunar valves
    - Pulmonary: between RV and pulmonary artery
    - Aortic: between LV and aorta
    - Consist of 3 cusps
    - Reversal of blood flow at end of ventricular systole snaps cusps together → prevents regurgitation of blood
  - o Sinuses of valsalva + eddy currents develop → prevent obstruction of coronary ostia

### *Coronary artery anatomy*

#### Coronary artery anatomy

- Heart receives 5% of CO = 250ml/min
- ventricular wall too thick for effective diffusion of O<sub>2</sub>:
  - o Endocardium nourished directly
  - o Bulk of cardiac muscle perfused by coronary circulation
- Coronary circulation
  - o divided into L + R
  - o Arise from aortic root at aortic sinuses (“sinuses of valsalva”)
  - o Eddy currents prevent valve cusps from occluding os of LM + RCA

#### LCA (L main stem)

- Origin: L posterior aortic sinus
- Course: along L AV groove → bifurcates into:
  - o 1. LAD
    - course: along anterior interventricular groove to apex
    - branches: septal + diagonal perforators
    - supplies:
      - anterolateral myocardium
      - apex
      - ant 2/3 of interventricular septum
  - o 2. L circumflex artery
    - course: L AV groove
    - branches: obtuse marginal branches

- anastomoses with terminal end of RCA
- supplies: posterolateral LV; SA in 40%

**RCA**

- Origin: anterior aortic sinus
- Course: along R AV groove
- Branches:
  - 1. **SA branch**: supplies SA node
  - 2. **R marginal artery**: along R margin of heart towards apex; supplies RV
  - 3. **Posterior interventricular artery** (posterior descending): supplies posterior septum + AV node
- continues in AV groove → anastomosis with L circumflex

**Coronary dominance**

- refers to the artery giving rise to the post interventricular artery
- Right dominant = PDA supplied by RCA; 60%
- Left dominant = PDA supplied by LCx; 20%

**Venous anatomy**

1. **coronary sinus**
  - a. Venous blood from LV collected by cardiac veins → coalesce to form coronary sinus → opens into RA
  - b. Cardiac veins: follow same path as arteries: include...
    - i. great cardiac vein: runs with LAD
    - ii. middle cardiac vein: follows PDA
    - iii. small cardiac vein: runs with RCA
    - iv. oblique vein: follows post part of LA
2. **anterior cardiac veins**: arise on ant surface of RV; drain into RA
3. **thebesian veins**: smallest; drain directly into 4 chambers of the heart

**Anatomy of excitatory and conductive elements: MAKEUP****Excitatory and conductive elements****General conduction arrangement**

- SA node → intermodal fibres → AV node → AV bundle L and R purkinje fibre branches
- Delay between SA depolarisation to AV node ~0.03s
- AV node → penetrating AV bundle delay ~0.09s
- AV penetrating to distal conduction a further ~0.04s delay
- Total time from SA node discharge to signal arrival at ventricles therefore ~0.16s

**SA node**

- normal cardiac pacemaker
- arises at junction of SVC + RA
- R vagus supplies SA (L vagus AV node) with SY innervation
- NA fibres are epicardial and Ach fibres are endocardial
- Ach acts presynaptically on SY nn → ↓NA release and NPY mayact to inhibit release of Ach
- An interatrial band conducts signals from R → L atrium

**AV node**

- located in post R atrial wall/ atrial septum, just above the opening of the coronary sinus
- receives connecting pathways from SA node
- signals arriving at the AV node travel to the penetrating and then distal portions of the AV bundle (bundle of His)
- unidirectional conduction normally

**Purkinje fibres**

- lead from the AV node through the AV bundle to the ventricular endocardium
- highly permeable gap junctions permits signal transmission at 1.5-4ms

**Autonomic innervation**

- arise from the VA (PSY) + cervical + upper thoracic SY ganglia
  - VA fibres = cardio-inhibitory → ↓rate of conduction of APs through AV node
  - SY fibres = cardio-accelerator → ↑rate of conduction of APs through AV node

## Electrical properties of the heart

### Ionic basis of automaticity the normal and abnormal processes of cardiac excitation

#### Pacemaker action potential

##### Background:

- **automaticity** = rhythmic depolarisation without external stimulation
  - o several ionic currents contribute to slow diastolic depolarisation that occurs in automatic cells in the heart
  - o outward K current; hyperpolarization induced inward current; inward  $\text{Ca}^{2+}$  current
- **cardiac pacemaker cells** = specialised cardiac myocytes whose spontaneous activity results in generation of APs
  - o Sites acting as pacemakers: SA + AV nodes
  - o NB ventricular myocytes may also display automaticity under pathological conditions e.g. ischaemia

##### Ionic basis of automaticity

- pacemaker cells exhibit automaticity
  - o have **no RMP** + undergo **spont depolarisation** → initiation of AP
  - o cardiac myocytes: phospholipid membrane – selective permeability to ions via ligand + voltage gated protein channels
  - o difference in conc across cell membrane create EC gradient

##### Phases of cardiac pacemaker AP:

- **Phase 4:**
  - o hyperpolarization-activated cyclic nucleotide gated (HCN) channels open →  $\text{Na}^{+}$  influx
  - o membrane hyperpolarization opens HCN channels →  $\text{Na}^{+}$  influx
  - o slow depolarisation of CM from  $-60\text{mV}$  to  $-40\text{mV}$
- **Phase 0: Depolarisation** via:
  - o voltage-gated T-type + L-type  **$\text{Ca}^{2+}$  channels** → inward  $\text{Ca}^{2+}$  current
- **Phase 3: Repolarisation** via
  - o **Inactivation** of funny, T-type + L type  $\text{Ca}^{2+}$  channels
  - o activation of K channels →  **$\text{K}^{+}$  efflux**
- **Phase 4:**
  - o Membrane potential returns to  $\sim -60\text{mV}$
  - o Funny channels reactivated + cycle repeats

##### Factors affecting automaticity

- **ANS**
  - o SA + AV node have ANS innervation
  - o SY stimulation via cardioaccelerator T1-T4 nerves → B1 adrenoceptors →  $\text{Gs}$  GPCR →  $\uparrow \text{cAMP}$  →  $\uparrow$  influx through funny currents (steeper phase 4) +  $\uparrow \text{Ca}^{2+}$  influx (steeper phase 0) →  $\uparrow \text{HR}$
  - o PSY innervation (via VA): action at M2 acetylcholine Rs →  $\text{Gi}$  GPCR →  $\downarrow \text{cAMP}$  →  $\downarrow \text{HR}$
- **Hypoxia**
  - o  $\downarrow \text{ATP}$  → inactivation of  $\text{Na}/\text{K}$  ATPase → unable to repolarize cell → automaticity lost
- **temperature**
  - o  $\uparrow \text{temp}$  →  $\uparrow$  actions of ion channels →  $\uparrow$  slope of phase 0 →  $\uparrow$  automaticity + HR
- **Age**
  - o Pacemaker cells infiltrated by fibrotic tissue →  $\downarrow$  automaticity →  $\downarrow$  max attainable HR

##### How does the pacemaker AP differ from that in cardiac myocytes?

|                             | Pacemaker AP                                                  | Cardiac muscle AP                                                    |
|-----------------------------|---------------------------------------------------------------|----------------------------------------------------------------------|
| Spontaneous depolarisation? | Yes                                                           | No                                                                   |
| Membrane potential          | $-60\text{mV}$                                                | $-90\text{mV}$                                                       |
| Threshold potential         | $-40\text{mV}$                                                | $-65\text{mV}$                                                       |
| Slope of phase 0 (depol)    | Less steep                                                    | Very steep                                                           |
| Depolarisation ion          | L-type $\text{Ca}^{2+}$ channels → $\text{Ca}^{2+}$ into cell | Fast $\text{Na}^{+}$ channels → $\text{Na}^{+}$ into cell            |
| Repolarisation              | Single phase (phase 3)                                        | Early rapid repolarization: phase 1<br>Final repolarization: phase 3 |
| Plateau?                    | No                                                            | Yes                                                                  |

#### Cardiac muscle action potential

- cardiac muscle is activated by AP generated by cardiac pacemaker cells
- propagation of AP between myocytes is facilitated by intercalated discs (gap junctions)

##### Phases

- **Phase 0 (rapid upstroke/ depolarisation)**
  - o threshold potential ( $-65\text{mV}$ ) reached
  - o fast voltage gated (outward M gate)  **$\text{Na}^{+}$  channels** open → rapid  $\text{Na}^{+}$  influx to  $+30\text{mV}$  → depolarisation
- **Phase 1: repolarization (partial)**
  - o  $\text{Na}^{+}$  channels close (inward H gate)
  - o  $\text{K}^{+}$  channels open → transient outward (repolarizing) K current
  - o No repolarization below  $0\text{mV}$
- **Phase 2: plateau phase**
  - o Inward current: voltage gated L type  $\text{Ca}^{2+}$  channels open →  $\text{Ca}^{2+}$  down EC gradient →  $\text{Ca}^{2+}$  influx
  - o Outward current: K efflux
  - o Allows for sustained contraction of ventricular muscle fibres necessary for ejection of blood from ventricles
- **Phase 3: repolarization**
  - o Voltage gated L type  $\text{Ca}^{2+}$  channels close
  - o K efflux unopposed → repolarization
- **Phase 4: RMP**
  - o RMP ( $-90\text{mV}$ ) maintained due to:
    - $\text{Na}/\text{K}/\text{ATPase}$  (3Na out; 2K in)
    - $\text{Na}/\text{Ca}^{2+}$  exchanger
  - o K conductance >  $\text{Na} + \text{Ca}^{2+}$  conductance → RMP

**Excitability:** ability of a cardiac muscle cell to reach hreshold in order to generate/ propagate an AP

- absolute refractory period (250ms):
  - o cell is not excitable due to closure of fast Na<sup>+</sup> channels (via m gate) + remain closed until -50mV
  - o phase 0,1,2, early 3
- Relative refractory period (further 50msec)
  - o Can excite cell to generate AP with supramaximal stimulus

### Abnormal cardiac excitation

- **↑automaticity:** may occur in SA, AV, and His-Purkinje system
- **ectopic foci:** atrial, nodal, or ventricular extrasystoles
- **Blocks**
  - o 1<sup>st</sup> degree
  - o 2<sup>nd</sup> degree
  - o RBBB / LBBB
  - o Interruption to SA node: 3<sup>rd</sup> degree
  - o Infranodal disease: ventricular PM 15-35BPM
- **atrial arrhythmia**
  - o Atrial tachycardia: regular discharge of an atrial focus or re-entrant activity → rates up to 220/min
  - o atrial flutter: 200-350/min; counter clockwise movement in RA; usually 2:1 block
  - o AF 300-500/min; irregular + disorganised; ↓diastolic time + loss of atrial component in diastole
- **accelerated AV conduction**
  - o WPW: bundle of Kent forms additional nodal or aberrant muscular connection between atria + ventricles
- **ventricular arrhythmia**
  - o Ventricular premature beats: ↑QRS due to slow impulse spread
  - o VF: irregular + ineffective discharge of multiple ventricular ectopic foci
- **After depolarisations + triggered automaticity**
  - o Delayed after depolarisation (DAD): intracellular Ca<sup>2+</sup> overload (myocardial ischaemia, adrenergic stress, digoxin toxicity, heart failure)
  - o Early after depolarisation (EAD): prolonged AP interrupting phase III repolarisation.
    - inward Na or Ca<sup>2+</sup> currents
    - More common with ↓HR, ↓K<sup>+</sup>, or drugs prolonging AP
    - Induced more readily in His-Purkinje system + mid myocardial
    - Torsades associated with EAD

**Threshold:** minimum level of membrane potential depolarisation required for an AP to occur: cardiac threshold = -65mV; pacemaker -40mV

**Excitability:** ability of a cardiac muscle cell to reach hreshold in order to generate/ propagate an AP

- absolute refractory period (250ms):
  - o cell is not excitable due to closure of fast Na<sup>+</sup> channels (via m gate) + remain closed until -50mV
  - o phase 0,1,2, early 3
- Relative refractory period (further 50msec)
  - o Can excite cell to generate AP with supramaximal stimulus

**Irritability:** ↑RMP usually due to ↑K<sup>+</sup>

- More likely to reach AP threshold as there is less difference between RMP and threshold potential with aberrant discharges more likely (arrhythmias)

### Physiological basis of the electrocardiograph in normal and common pathological states

#### Normal ECG

|             | Details                                                                                                                                                                                                                                                                                                                                                                                                                    | Normal duration                 | Pathology                                                        |

- Potential difference between pairs of electrodes = lead
  - o Each lead views electrical activity in heart from different angle
  - o Limb leads: electrodes on R arm, L arm, L leg
  - o Augmented limb leads (aVF, aVR, aVL):
  - o 6 precordial leads (V1-V6)
  - o +ve and -ve deflections indicate net electrical current flow towards + away from electrode
- Cardiac axis
  - o Leads that view heart in coronal plane (6 limb leads + augmented limb leads) can be used to determine cardiac axis = net direction (or vector)
  - o Axis -30° = L axis deviation → LVH
  - o Axis +90° = R axis deviation → RVH

Figure 55.3 Vectors of the ECG leads.

#### Link the coronary circulation to leads of an ECG

- The leads of an ECG view different surfaces of the heart which are supplied by different arteries.
- Leads II, III, aVF = inferior surface of the heart → usually RCA or distal circumflex
- Leads V1 to V4 = anterior surface → LAD
- Leads I, aVL, V6 = lateral surface → proximal circumflex artery
- V1 and aVR = RA and cavity of LV

#### The normal ECG with a "fast fibre" AP superimposed

#### ECG + myocardial ischaemia

- Extent of myocardial ischaemia
  - o subendocardial ischaemia/ infarction → ST depression
  - o subpicardial or transmural infarction → ST elevation
- Location of ischaemia

| Location of ischaemia | Leads affected | Supplied by                                                     | Effect of occlusion                                            |
|-----------------------|----------------|-----------------------------------------------------------------|----------------------------------------------------------------|
| Inferior wall         | II, III, aVF   | RCA                                                             | As RCA supplies SA node: occlusion → hypotension + bradycardia |
| Lateral wall          | I, II, V5      | Circumflex                                                      | LV dysfunction                                                 |
| Septal                | V1, V2         | Septal branch L interventricular a                              | As interventricular septum is site of bundle of His → BBB      |
| Apical                | V3, V4         | Terminal portion of L interventricular a<br>If R dominant: post |                                                                |

|                |                              |                                      |                                                                              |
|----------------|------------------------------|--------------------------------------|------------------------------------------------------------------------------|
|                |                              | interventricular a                   |                                                                              |
| Anterior wall  | Can affect:<br>I, aVL, V1-V6 | L interventricular a                 | Complete occlusion: ischaemia of large portion of LV → severe LV dysfunction |
| Posterior wall | ST depression V1-V4          | Circumflex + post interventricular a | L ventricular dysfunction                                                    |

### Factors that may influence cardiac electrical activity

#### - ANS

- SY:
  - via NAd at B1 receptors: ↑HR by ↑rate of phase 4 depolarisation via ↑Na<sup>+</sup> influx during phase 4
  - ↑Ca<sup>2+</sup> influx which ↑ conduction through AV node → ↓PR interval (+ve dromotropic effect)
- PSY:
  - ACh acting on muscarinic Rs → ↓HR by ↓Na<sup>+</sup> influx + therefore extending phase 4 duration in the slow response myocytes + ↓Ca<sup>2+</sup> influx which slows conduction through the AV node

#### - Endocrine: Adrenaline; Noradrenaline ; Thyroxine

#### - Metabolic

- Na: ↓Na<sup>+</sup> → ↓voltage ECG complexes
- ↑K:
  - tall T waves – manifestation of paralysis of the atria + prolongation of the QRS complexes
  - ventricular arrhythmias
  - RMP ↓s as K↑s
  - Prominent U waves
- Ca<sup>2+</sup>:
  - ↑Ca<sup>2+</sup>: ↑myocardial contractility; shortening of QT interval due to shorter ST segment
  - ↓Ca<sup>2+</sup>: ST prolongation → QT prolongation
- Mg<sup>2+</sup>
  - ↓Mg: widening QRS; peaked T waves; prolongation of PR interval

#### - Temperature: ↑temp → ↑HR; ↓temp → ↓HR

#### - Drugs

- Adenosine:
  - Adenosine Rs in atrial + nodal tissues
  - Activate K<sup>+</sup> current which transiently hyperpolarises the cell → drives SA and AV nodal tissue further from threshold and → slows rate
  - Antagonises adenylyl cyclase → ↓intracellular Ca<sup>2+</sup> → slows conduction
  - Transient AV node block

#### - Pathology

### Describe the autonomic innervation of the heart and the direct effect of autonomic stimulation on cardiac function: PAST QUESTION

- ANS = portion of nervous system that regulates involuntary control of most organs (including heart)
- Heart has SY + PSY innervation
  - SY: mediated by NAd → stimulation results in ↑HR + ↑contractility
  - PSY: mediated by ACh → stimulation results in ↓HR; no effect on contractility (as ventricular muscle not supplied)

| Property                               | SY                                                                                                                                                   | PSY                                                                                                                      |
|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|

(a) Parasympathetic stimulation – HR decreases

(b) Sympathetic stimulation – HR increases

### Cardiac cycle: correlation of the mechanical events of the cardiac cycle with the electrical and ionic events

#### The cardiac cycle

The cardiac cycle describes the events that occur during one heartbeat.

- 2 phases → divided into 6 stages

#### 1. Diastolic phase – ventricles fill with blood; 4 stages:

- Isovolumetric relaxation
- Rapid ventricular filling
- Slow ventricular filling (start of cycle)
- Atrial contraction

#### 2. Systolic phase – ventricles contract and eject blood into aorta and pulmonary artery; 2 stages:

- Isovolumetric contraction
- Ejection

- NB: a cycle begins in late diastole when the myocardium is relaxed and the ventricles are passively filling

#### Cycle:

| Phase                                   | Details                                                                                                                                                                                                                                             | ECG                  | CVP                                           |
|-----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------|-----------------------------------------------|
| 1. Slow ventricular filling (diastole)  | Atrial pressure > ventricular pressure<br>AV valves open → blood flows from atria to ventricles                                                                                                                                                     | P wave               |                                               |
| 2. Atrial contraction (diastole)        | Atrial "kick" → ~20% ventricular filling<br>Vol of blood in ventricle at end of atrial contraction = EDV                                                                                                                                            | PR interval          | a wave: small pressure wave in great veins    |
| 3. Isovolumetric contraction (systole)  | time between closure of AV valves → opening of aortic + pulmonary valves<br>ventricular pressure ↑ without Δventricular vol                                                                                                                         | Start of QT interval | c wave: ↑RV pressure → TV bulges into RA      |
| 4. Ejection (systole)                   | Ventricular P > aorta/ pulmonary P → semilunar valves open<br>1. Rapid ejection<br>2. Reduced ejection<br>eventually ventricular P < aortic/ pulmonary pressure → semilunar valves close<br>Vol of blood within ventricle after valve closure = ESV | ST segment           | x descent: shortening RV pulls RA down → ↓CVP |
| 5. isovolumetric relaxation (diastole)  | Initially AV valves remain closed as the pressure in ventricles > atrium                                                                                                                                                                            |                      | v wave: atrial pressure ↑s due to VR          |
| 6. Rapid ventricular filling (diastole) | Atrial pressure > ventricular pressure → AV valves open → blood from atria to ventricles                                                                                                                                                            |                      | y descent: ↓atrial pressure                   |

### Describe the physiology of cardiac muscle and the mechanism of excitation contraction coupling

#### Cardiac muscle

- Special intrinsic properties:
  - o Excitability
  - o Automaticity
  - o Rhythmicity
  - o Conductivity
  - o Contractility
- not all cardiac myocytes are contractile:
  - o atrial + ventricular myocardial cells: capable of contraction + conduction of excitation
  - o pacemaker + conducting cells: excitable but non-contractile
    - pacemaker cells: SA + AV node → generate spontaneous cardiac AP
    - conducting cells: Purkinje fibres → spread cardiac AP around ventricles
- Features of cardiac myocytes:
  - o Striated appearance: thick + thin filaments within sarcoplasm
  - o Sarcotubular system: T tubules + SR
  - o Involuntary control: ANS + endocrine modulate function
  - o Gap junctions: ↓resistance electrical connections → rapid conduction of APs throughout myocardium → functional syncytium

#### How are APs conducted through the heart?

- ensures synchronous contraction of ventricular myocytes
- APs generated in SA node are conducted via:
  - o Internodal pathways:
    - relayed from SA to AV node
    - 3 pathways: anterior (Bachmann), middle (Wenkebach), posterior (thorel)

- AV node
  - Transmits AP between atria + ventricles
  - Elsewhere junction between A + V is insulated by annulus fibrosus
  - AV nodal delay → PR interval
- Bundle of His
  - R + L branches
  - L branch → L anterior + L posterior fascicles
- Purkinje fibres
  - Synchronise ventricular activation
- Cardiac myocytes
  - Mechanical + electrical connections
    - Connected end to end by intercalated discs → functional syncytium
    - Gap junctions: allow AP to pass between myocytes

### Excitation contraction coupling

- Process by which the electrical stimulus (AP) of myocyte is converted to a mechanical response
  - **1. Ca<sup>2+</sup> induced Ca<sup>2+</sup> release**
    - AP at sarcolemma → membrane depolarisation → L-type Ca<sup>2+</sup> channels open → Ca<sup>2+</sup> from ECF to sarcoplasm
    - SR of cardiac muscle contains RyRs: Ca<sup>2+</sup> influx opens RyR → SR releases Ca<sup>2+</sup> → “Ca<sup>2+</sup> induced Ca<sup>2+</sup> release”
  - **2. Activation of cross bridging:**
    - Ca<sup>2+</sup> binds to troponin C → conformational change in tropomyosin → uncovers myosin binding site on actin → myosin binds + forms cross bridge with actin
    - Cross bridge cycling occurs, powered by ATP hydrolysis → sarcomere shortening
    - Continues until cytoplasmic [Ca<sup>2+</sup>] ↓ during repolarization
  - **3. Termination of cardiac contraction**
    - as SR [Ca<sup>2+</sup>] ↓s, Ca<sup>2+</sup> dissociates from troponin C → tropomyosin recovers actin binding site
    - actively removing Ca<sup>2+</sup> from the cell
      - **Ca<sup>2+</sup> ATPase pump:** primary active transport to remove Ca<sup>2+</sup> from cell
      - **Na/Ca<sup>2+</sup> exchanger:** 1 Ca<sup>2+</sup> out: 3Na<sup>+</sup> in. efflux of Ca<sup>2+</sup> occurs down conc gradient and is driven by the low intracellular [Na<sup>+</sup>] due to Na/K ATPase pump (i.e. secondary active transport)
      - **Sarcoplasmic/ ER Ca<sup>2+</sup> ATPase pump (SERCA):** sequesters Ca<sup>2+</sup> in the SR

## Determinants and control of cardiac output including implications for clinical practice

### Frank Starling mechanism

- **Frank Starling mechanism = intrinsic ability of the heart to alter its force of contraction in response to ΔVR**
  - Relates myocardial sarcomere fibre length (or index thereof: LVEDV, LVEDP, CVP) to force generated (or index thereof: SV, LV pressure)
  - Simplest form: ↑VR → ↑LVEDV (preload) → ↑force of contraction; i.e. ↑LVEDV → ↑SV (to a point)
- attributed to **length-tension relationship**
  - Degree of overlap of actin + myosin myofilaments in diastole → determines extent of crossbridge formation on activation and therefore strength of contraction
  - Sarcomere length:
    - Peak effect at **2.2μm** → number of actin + myosin crossbridges is high → max force of contraction = LVEDP ~10-12mmHg
    - <2.2μm; i.e. ↓EDV → ↓tension generated → contractile energy lost due to work against friction; sarcomere distorted
    - >2.2μm: ↓actin-myosin crossbridges formed → ↓contraction (can occur in HF)
- The Frank Starling mechanism is represented by the **ventricular function curve** → plots preload against SV (or CO)
  - Family of curves when afterload or inotropy are varied
    - R shift = -ve inotropy
    - L shift = +ve inotropy

### Relationship to excitation contraction coupling

- Excitation-contraction coupling = process of converting electrical stimulus (AP) into mechanical response (contraction)
  - Explained by **sliding filament theory**:
  - AP arrives at cardiac myocyte → depolarisation → Ca<sup>2+</sup> influx → Ca<sup>2+</sup> induced Ca<sup>2+</sup> release from SR via ryanodine Rs → Ca<sup>2+</sup> binds troponin C → removes inhibitory tropomyosin from actin → actin-myosin cross bridge cycle → actin and myosin filaments slide over each other = contraction
- Strength of contraction depends on initial sarcomere length
  - LV sarcomere resting length (healthy heart) = 1.8μm
  - LV sarcomere length for optimal overlap = 2.2μm
  - More optimal sarcomere length at end diastole →
    - **optimization of actin/ myosin overlap + maximizes cross bridge formation**
    - **↑sensitivity of myofilaments to Ca<sup>2+</sup>**
    - **↑affinity for Ca<sup>2+</sup> of troponin C**
    - **More force generated**
  - NB excessive stretching → overstretching of LV sarcomeres → ↓force of contraction

**Cardiac output**

CO = vol of blood ejected by the L or R ventricle per minute

- **CO = SV x HR**
  - o **HR**
    - set by SA node pacemaker activity → modulated by ANS
    - At rest: PSY tonically active → ACh continually released from PSY nerve terminals → resting HR 60-70bpm
    - Bradycardia → ↓CO
    - Tachycardia → ↑CO up to a point; >150bpm: diastolic time short (~0.15s) → ↓ventricular filling → ↓SV → ↓CO
  - o **SV**
    - Vol of blood ejected from LV per heart beat
      - Vol of blood in LV prior to contraction = LVEDV
      - Vol of blood remaining in LV after contraction = LVESV
      - **SV = LVEDV – LVESV** → Typical values: LVEDV = 120ml; LVESV = 50ml → SV = 70ml
    - dependent on preload, afterload, cardiac contractility
- NB EF = proportion of blood ejected from LV per heart beat: EF = SV / LVEDV

**Measurement of CO**

- **invasive:** PAC, CVC, or art line
  - o **Fick principle:**
    - Based on law of conservation of mass
    - The amount of an indicator substance taken up per unit time = arterio-venous difference of substance x blood flow
    - $Q = VO_2 / CaO_2 - CvO_2$ 
      - normal value: CO = 250ml/min / 0.2 (ml O<sub>2</sub> per ml blood) – 0.15 = 5000ml/min
  - o Methods based on Fick principle:
    - **Dye dilution method:**
      - Known amount of indicator dye (e.g. lithium) injected directly into pulmonary artery → concentration continuously sampled at peripheral arterial line → Δconcentration over time recorded as graph → CO calculated from AUC
      - CO = amount of indicator / AUC – time graph
    - **Thermodilution method:**
      - PAC with thermistor at tip → cold saline injected via proximal lumen into RA → Δpulmonary arterial blood temp measured by thermistor → temperature-time graph
      - CO calculated using modified Stewart-Hamilton Equation
  - o **Pulse contour analysis** e.g. **PiCCO** (pulse contour cardiac output)
    - Morphology of arterial pressure waveform related to SV and SVR
    - Uses central line + thermistor tipped arterial line sited at femoral/ brachial/ axillary artery
    - CO estimated by analysis of arterial pressure waveform
    - Calibrated using transpulmonary thermodilution method – cold saline injected into CVC and Δblood temp detected at arterial line
- **minimally invasive:**
  - o Based on proximity of heart and great vessels to oesophagus
  - o **Oesophageal doppler:**
    - US transducer into oesophagus alongside descending aorta → beam reflects off RBC at different frequencies (Doppler principle)
    - Using doppler equation the velocity of blood flow within descending thoracic aorta can be calculated
    - CO calculated from aortic blood flow on the basis that 70% of SV passes through the descending thoracic aorta
  - o **TOE**
    - CO calculated in 2 ways:
      1. Estimated volumes (EDV and ESV estimated);
      2. doppler: blood flow measured across LVOT using doppler principle + measured cross sectional area
- **Non invasive:** TTE, MRI

**Preload**

- myocardial sarcomere length just prior to contraction
- according to **Frank Starling's** law of the heart: the force of cardiac myocyte contraction depends on preceding diastolic length of the ventricular fibres
  - o At cellular level: additional stretch → ↑number of myofilament crossbridges that interact and ↑myofilament Ca<sup>2+</sup> sensitivity
  - o Represented by ventricular function curve: plots preload against SV
- sarcomere length is not measureable → so clinically it is approximated by:
  - o EDV (measured by ECHO)
  - o EDP (measured using CVC or PAC); NB relationship between EDV and EDP depends on ventricular compliance
- ↑preload → ↑EDV → ↑ED fibre length of ventricular muscle → ↑velocity of muscle shortening for given afterload → ↑blood ejected
- Determinants of preload. Preload is a function of:
  - o VR:
    - intrathoracic pressure: -ve pressure → ↓RAP and ↓PCWP → ↑RA filling
    - MSFP → ↑VR → ↑EDV
  - o Ventricular compliance: ↓compliance → ↓filling e.g. diastolic dysfunction, AMI
  - o Pericardial compliance: ↑intrapericardial P → ↓ventricular filling
  - o Valvular disease: AV disease will impair preload; semilunar valve disease will ↑preload
  - o Atrial kick
  - o Wall thickness: ↑ventricular wall thickness → ↓preload e.g. HOCM

**Afterload**

**Describe the factors that oppose left ventricular ejection fraction (PAST QUESTION)**

- Afterload = sum of forces that oppose LV output i.e. ventricular wall tension during contraction required to overcome impedance to ejection of blood into arterial circulation
- according to **Law of Laplace:**
  - o **wall tension = transmural pressure x radius / 2x wall thickness**
  - o transmural pressure = intracavity pressure – intrapleural pressure

Factors that determine afterload

- **L ventricular wall tension**

- LV transmural pressure
  - E.g.  $\uparrow$ ITP  $\rightarrow$   $\downarrow$ transmural pressure  $\rightarrow$   $\downarrow$ afterload e.g. IPPV
  - E.g.  $\downarrow$ ITP  $\rightarrow$   $\uparrow$ transmural pressure  $\rightarrow$   $\uparrow$ afterload
- LV radius
- LV wall thickness
- **SVR**
  - SVR = Resistance to blood flow by systemic vasculature
  - Heart = demand pump: blood flow autoregulated by tissues
  - Arterioles = main determinant of SVR
  - **Hagen-Poiseuille:  $R = 8nl / \pi r^4$**  where R is resistance; n = viscosity; l = length of tube; r = radius
    - Radius has most effect on SVR
    - Arteriolar caliber governed by:
      - Neural control: SY
      - Myogenic autoregulation: reflex arteriolar contraction in response to  $\uparrow$ stretch of wall to limit pressure to tissue
      - Metabolic autoregulation: release of vasoactive substances with  $\uparrow$ metabolites,  $\downarrow$ pH,  $\downarrow$ pO<sub>2</sub>,  $\uparrow$ K<sup>+</sup>
      - Temperature:  $\uparrow$ temp  $\rightarrow$  vasodilation
      - Age:  $\uparrow$ age  $\rightarrow$   $\uparrow$ SVR
- **L ventricular outflow tract resistance/ aortic root pressure**
  - Hagen-Poiseuille:  $\downarrow$ calibre  $\rightarrow$   $\uparrow$ resistance  $\rightarrow$   $\uparrow$ afterload e.g. aortic stenosis
- **Aortic root compliance/ aortic root pressure**
  - $\downarrow$ compliance (e.g. atherosclerosis, ageing)  $\rightarrow$   $\downarrow$ SV stored as elastic recoil of arteries  $\rightarrow$   $\uparrow$ pulse pressure  $\rightarrow$   $\uparrow$ work required by heart to pump a given ejection fraction  $\rightarrow$   $\uparrow$ afterload

#### Effect of sudden $\uparrow$ afterload

- time dependent process
- **immediate**
  - $\downarrow$ SV,  $\downarrow$ CO
  - $\uparrow$ ESV
  - $\uparrow$ SBP and LVESP
- **5-15mins**
  - Frank-Starling mechanism  $\rightarrow$   $\uparrow$ preload  $\rightarrow$   $\uparrow$ CO
  - Anrep effect:  $\uparrow$ sensitivity to Ca<sup>2+</sup>  $\rightarrow$   $\uparrow$ CO
- **$\uparrow$ afterload  $\rightarrow$** 
  - $\downarrow$ rate and  $\downarrow$ extent of sarcomere shortening  $\rightarrow$   $\downarrow$ SV  $\rightarrow$   $\uparrow$ LVEDV  $\rightarrow$  according to Starling's law:  $\uparrow$ LVEDV  $\rightarrow$   $\uparrow$ SV. E.g.: sudden  $\uparrow$ afterload  $\rightarrow$   $\downarrow$ SV transiently before returning to normal
  - **Anrep effect:**  $\uparrow$ afterload  $\rightarrow$  intrinsic  $\uparrow$ inotropy  $\rightarrow$  smaller  $\downarrow$ SV than would be predicted from the Frank-Starling mechanism alone
  - $\uparrow$ myocardial O<sub>2</sub> demand

#### Myocardial contractility

- **intrinsic ability of cardiac myocytes to shorten, independent of preload and afterload**
- Factors that  $\uparrow$ contractility = +ve inotropic effect (shift FS curve up + left);  $\downarrow$ contractility = -ve inotropic effect (shift FS curve down + right)
- Index of myocardial contractility is provided by the rate of  $\Delta$ pressure (i.e. gradient) during the isovolumetric contraction phase of cardiac cycle
- Primarily dependent on intracellular Ca<sup>2+</sup>

#### Determinants of contractility

- **1. SYNS:** NA from cardiac SY neurons  $\rightarrow$   $\uparrow$ contractility through action of B1 adrenoceptors
- **2. Tachycardia:**  $\uparrow$ HR  $\rightarrow$   $\uparrow$ contractility = Bowditch effect
  - Bowditch effect:
    - intrinsic autoregulatory phenomenon in which tachycardia  $\rightarrow$   $\uparrow$ myocardial contractility
    - Mechanism:  $\uparrow$ HR  $\rightarrow$   $\uparrow$ Ca<sup>2+</sup> influx  $\rightarrow$  Na<sup>+</sup> efflux by Na/K/ATPase cannot keep pace with systolic influx of Na  $\rightarrow$   $\uparrow$ intracellular Ca<sup>2+</sup>  $\rightarrow$  +ve inotropic effect
- **3. Drugs with +ve inotropic effects:** dopamine, isoprenaline, glucagon, digoxin; -ve inotropic effects: CCB, BB, anaesthetics
- **4. Disease states:** sepsis, myocarditis, IHD, electrolyte and acid-base disturbance

#### Cardiac output and vascular function curves

##### Cardiac function curve:

- **expression of Frank-Starling relationship**
- CO depends on RAP (CVP)

##### Vascular function curve

- **analyse interactions between heart + vasculature**
- shows how a  $\Delta$ CO causes an inverse  $\Delta$ CVP
  - when CO is suddenly  $\downarrow$   $\rightarrow$  the rate at which blood flows from arteries to veins is temporarily  $>$  rate at which the heart pumps blood from the veins back to the arteries  $\rightarrow$  net vol of blood transferred from arteries to veins  $\rightarrow$   $\downarrow$ Pa and  $\uparrow$ Pv
- **depends on:**
  - **TPR:** Pv varies inversely with TPR
    - Arteriolar tone:  $\downarrow$ tone  $\rightarrow$   $\downarrow$ resistance to VR  $\rightarrow$   $\uparrow$ VR
    - SNS  $\rightarrow$   $\uparrow$ tone  $\rightarrow$   $\downarrow$ VR
  - **Arterial and venous compliance**
  - **Blood volume**
  - **MSFP**
    - Blood volume:
      - Hypervolaemia shifts vascular function curve up + right  $\rightarrow$   $\uparrow$ MSFP reflecting overfilling of circulation. Cardiac function curve not affected. Net result =  $\uparrow$ RAP + VR
      - Hypovolaemia:  $\downarrow$ MSFP,  $\downarrow$ RAP,  $\downarrow$ VR
    - Venous tone
    - Muscle pump: muscular contraction compresses veins  $\rightarrow$  promotes forwards flow  $\rightarrow$   $\uparrow$ MSFP
  - **Posture**
    - Blood pools in venous capacitance system

- 14

### Left ventricular pressure volume relationship

#### Contractility and PV loop

- $\uparrow$  myocardial contractility  $\rightarrow \uparrow$  gradient of the slope of the ESPV + widening of PV loop
- Unlike the widening of the PV loop caused by  $\uparrow$  preload (which moves the end diastolic point to the R),  $\uparrow$  contractility widens PV loop by shifting end systolic point to the L

### Left ventricular pressure volume relationship

#### PV loop in ischaemic heart

- PV loop leans to **right**
  - o due to early lengthening of ventricular fibres during isovolumetric contraction phase of systole that is not normally seen.
  - o caused by bulging of the area of ischaemic muscle.
  - o Hence, during isovolumetric contraction  $\rightarrow$  pressure + vol  $\uparrow \rightarrow$  loop leans to the right
- during isovolumetric relaxation phase of diastole there is post systolic shortening of the ventricular muscle fibres caused by active shortening or elastic recoil of the ventricle with profound ischaemia  $\rightarrow$  this  $\downarrow$  vol +  $\downarrow$  pressure within the ventricle.

#### Determinants of venous return + effect of GA: PAST QUESTION

- VR = vol of blood returning to the RA per minute + matches the CO
- Normal value = 5L/min
- Using derivation of Ohms Law ( $V = IR$ )
  - o  $VR = (MSFP - RAP) / \text{venous resistance}$
  - o MSFP = mean systemic filling pressures  $\rightarrow$  normal value 7mmHg
  - o RAP = RA pressure  $\rightarrow$  normal value 0mmHg
  - o Venous resistance = resistance of venous return

#### Determinants

- **MSFP**
  - o Normal value = 7mmHg
  - o When MSFP = RAP  $\rightarrow$  flow ceases
  - o  $\uparrow$  blood vol;  $\uparrow$  venous tone, muscle pump  $\rightarrow \uparrow$  MSFP
  - o Affect of GA:
    - Venodilation  $\rightarrow \downarrow$  venous tone  $\rightarrow \downarrow$  MSFP  $\rightarrow \downarrow$  VR
    - Fasting  $\rightarrow \downarrow$  vol  $\rightarrow \downarrow$  VR
    - GA + stasis  $\rightarrow \downarrow$  MSFP  $\rightarrow \downarrow$  VR
- **RAP**
  - o Thoracic pump during respiration  $\rightarrow$  -ve ITP  $\rightarrow \uparrow$  VR
  - o GA: IPPV  $\rightarrow$  +ve ITP  $\rightarrow \downarrow$  VR
- **Venous resistance**
  - o Arteriolar tone:  $\downarrow$  tone =  $\downarrow$  resistance to VR  $\rightarrow \uparrow$  VR
  - o SNS effect on arteriolar tone:  $\uparrow$  SYS  $\rightarrow \uparrow$  tone  $\rightarrow \downarrow$  VR

### - Other factors

- Patient positioning
  - Upright: ↓VR due to effect of gravity with loss of muscle pump
  - Trendelenburg: head down ↑VR due to favourable effect of gravity
  - Lithotomy: ↑intraabdominal pressure → ↓VR
- Pneumoperitoneum
  - +ve intrabdominal pressure → ↑RVR → ↓VR

### Relationship between CO and VR: PAST QUESTION

- R + L circuits pump in series; maintenance of stable circulation requires rapid equilibration between VR and CO
- Measurement of the same flow at different point in a series circuit
- Cannot differ for more than a few heartbeats before new equilibrium is reached
- Frank starling law: strength of cardiac contraction dependent upon initial fibre length of cardiac sarcomere → heart intrinsically adjust CO for ΔVR

| Factors affecting vascular function curve                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Factors affecting cardiac function curve                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

### Interaction of both:

- relationship between curves is the coupling between the heart and the peripheral circulation
- point where the 2 curves cross = equilibrium point; this defines the CO and the RAP at which the CVS operates
- normal: CO 5L/min; RAP 0mmHg
- ↑Vol: cardiac function curve unchanged, venous curve shifted up and right
- ↑afterload
  - venous curve: ↑MSFP: ↑RAP essentially same (no change in position); ↑TPR so ↓gradient of curve
  - cardiac function curve: ↑afterload ↓SV for given preload and contractility → curve shifted down and to right
  - intersection of curves drops and shifts to right → ↓CO for given RAP

## Coronary blood flow

### Myocardial oxygen supply and demand

#### Summary:

| Myocardial O2 demand                                                                         | Myocardial O2 supply                                                                                                                                                                                      | Myocardial O2 extraction                                                                                        |

NB: ADP = aortic diastolic pressure

Coronary blood flow (MAKEUP)

- Heart supplied by coronary circulation
  - o Aortic root → coronary sinus → L + R coronary arteries + branches → capillaries → veins → coronary sinus + anterior cardiac veins → RA
  - o Thebesian veins drain capillaries → cardiac chambers
- Generally:
  - o LCA supplies L side of heart + septum + part of posterior
  - o RCA supplies R side of heart + part of septum + posterior
- CorBF
  - o vol of blood flowing through the coronary circulation per unit time
    - Resting CorBF = 250ml/min or 5% CO
    - 80% CorBF + O<sub>2</sub> supply occurs during diastole
  - o Based on Ohm's law: flow = pressure / resistance. Therefore: **CorBF = CorPP / CVR**
- Heart is highly metabolic; high O<sub>2</sub> extraction ratio of ~70% at rest → therefore O<sub>2</sub> delivery can only be significantly ↑ by ↑CorBF

Coronary blood flow is dependent on:**1. CorPP**

- o Driving pressure for coronary circulation; Starling resistor
- o **CorPP = ADP – LVDP** (or RAP → whichever is greater) → LVDP and RAP <<< ADP → therefore CPP ~ = ADP
- o Dependent on:
  - **Arterial pressure:** Depends on CO, SVR; ↓arterial pressure → ↓CorPP
  - **Intraventricular pressure:** ↑intraventricular pressure → ↓CorPP
  - **Coronary sinus / RAP**

**2. Coronary vascular resistance**

- o Governed by Poiseuille equation:  $R = 8\eta L/\pi r^4$
- o Governed by factors that alter coronary artery radius:
  - Metabolic autoregulation: vasodilator (NO, PGI<sub>2</sub>) release triggered by local metabolites (↓O<sub>2</sub>, ↑CO<sub>2</sub>, ↑H, ↑K, ↑adenosine)
  - Myogenic autoregulation: smooth muscle stretch → contraction
  - Autonomic + hormonal control: SNS, PSNS, adrenaline, ADH
  - Extrinsic compression
  - Intrinsic narrowing: CAD, vasospasm
- o Coronary artery = Starling resistor → caliber of vessels ↓ with ↑ intraventricular pressure which comp

**3. Heart rate**

- o Tachycardia ↓diastolic time → ↓LV CorBF

**4. Variation throughout the cardiac cycle**

- o CorPP and CorVR varies with cardiac cycle
- o Systole: ↓CorPP; ↑CorVR → ↓CorBF
- o Diastole: ↑CorPP; ↓CorVR → ↑CorBF

**5. Variation between LV e.g. RV**

- o LV: large difference between CorPP in systole and diastole
  - Systole: LV pressure > coronary arterial pressure → intramuscular arterioles compressed
  - Diastole: LV pressure < coronary arterial pressure → blood flow to myocardium
  - minimal CorBF during systole → LV perfusion mainly in diastole
- o RV: smaller difference between CorPP in systole and diastole → CorBF continuous + maintained in s

Regulation/ control of coronary blood flow:**1. Autoregulated (60-180mmHg)**

- o **Myogenic**
  - ↑transmural P → ↑leakiness smooth muscle membranes → depolarisation
  - resistance ↑s proportionally to pressure → flow remains constant
- o **Metabolic (1° mechanism)**
  - **CorBF tightly coupled to O<sub>2</sub> demand**
  - ↑cardiac work / anaerobic metabolism → ↓myocardial ATP + ↑AMP + **adenosine** released from myocardial cells → vasodilation of coronary arterioles → ↑CorBF
  - Other vasodilatory mediators: local metabolites = ↓O<sub>2</sub>, ↑CO<sub>2</sub>, ↑H, ↑K

**2. Autonomic / hormonal control**

- o Direct: PSY + SY innervation of coronary vessels: ACh, Nad, Ad
- o Indirect: autoregulation occurring with Δmyocardial work in response to PSY or SY stimuli

**Summary:**

Therefore: main factors that influence CorBF are:

- Coronary perfusion pressure
  - o arterial pressure
  - o intraventricular pressure
- coronary vascular resistance
  - o Governed by Hagen-Poiseuille law
  - o Regulation of coronary vessel radius depends on:
    - Metabolic control
    - Myogenic control
    - Humoral control
    - Neural control
- Heart rate
- cardiac cycle
- LV e.g. RV
- Myogenic autoregulation
- Metabolic autoregulation: O<sub>2</sub> demand
- Autonomic/ hormonal control

**NB:**

- ADP: aortic diastolic pressure
- LVDP: LV diastolic pressure

- RAP: R atrial pressure

Methods to measure coronary blood flow – see “measurement of CO”

- Fick principle: flow = uptake of a substance / arterio-venous difference
- Thermodilution technique
- Thallium scanning or coronary angio: may indicate differences in regional flow

Methods of  $\uparrow$  coronary blood flow in pts with IHD

- GTN  $\rightarrow$  coronary vasodilation
- B blockers  $\rightarrow$  slow HR  $\rightarrow$  allows  $\uparrow$  time for diastole
- CABG and angioplasty may improve or bypass areas of inadequate flow

### Coronary blood flow and variation throughout the cardiac cycle: MAKEUP

- Coronary arteries run along epicardial surface  $\rightarrow$  arterioles penetrate into the myocardium at  $\sim$ right angle
- CorPP and CorVR varies with cardiac cycle
- LV
  - o Blood flow is intermittent
  - o **Systole:** pressure within contracting muscle of LV  $>$  coronary arterial pressure  $\rightarrow$  intramuscular arterioles compressed  $\rightarrow$  prevent blood flow to myocardium
  - o **Diastole:** heart relaxes  $\rightarrow$   $\downarrow$  pressure
- RV
  - o Pressure generated within RV  $<$  LV
  - o RV myocardium perfused throughout the cardiac cycle

### Outline the factors that determine coronary vascular resistance: PAST QUESTION

Heart muscle supplied by coronary circulation

- Aortic root  $\rightarrow$ 
  - o LCA supplies L heart + septum
  - o RCA supplies R heart + septum

Determinants of CVR

- Governed by Hagen-Poiseuille equation:  $R = 8\eta L / \pi r^4$ 
  - o  $\eta$  = viscosity
  - o  $L$  = length
  - o  $r$  = radius

#### 1. Radius has main effect: factors that alter coronary artery radius:

##### i. Metabolic autoregulation:

- Most important form of autoregulation
- Release of vasoactive substances (NO, PGI<sub>2</sub>) in response to metabolite production ( $\downarrow$ O<sub>2</sub>,  $\uparrow$ CO<sub>2</sub>,  $\uparrow$ H<sup>+</sup>,  $\uparrow$ K<sup>+</sup>,  $\uparrow$ adenosine)  $\rightarrow$  vasodilation

##### ii. Myogenic autoregulation:

- Operates to maintain CorPP
- Changes between: 60-180mmHg counteracted by vasodilation/ constriction to maintain flow
- smooth muscle stretch  $\rightarrow$  contraction

##### iii. Autonomic + hormonal control:

- SNS: chronotropy + inotropy  $\rightarrow$   $\uparrow$ metabolic demands of heart
  - Vasodilation via  $\beta$ -adrenoceptors  $\rightarrow$   $\uparrow$ CBF to meet requirements
  - $\alpha$ -adrenoceptors  $\rightarrow$  vasoconstriction  $\rightarrow$   $\downarrow$ CBF
- PSNS
  - Vasodilation + bradycardia
- adrenaline, ADH

##### iv. Extrinsic compression

- Starling resistor mechanism: caliber of vessels  $\downarrow$  with  $\uparrow$ intraventricular pressure which compresses the vessels overlying it  $\rightarrow$  interrupt flow
- $R = \text{CorPP} / \text{CorBF}$
- $\text{CorPP} = \text{aortic diastolic pressure} - \text{LVDP} / \text{CVR}$
- $\uparrow$ intraventricular pressure during systole: LV  $>$  RV

v. **Intrinsic narrowing:**

- CAD, vasospasm

**2. Viscosity**

- $\uparrow$ viscosity  $\rightarrow \downarrow$ CBF (e.g.  $\uparrow$ Hct)

**3. CPP and CorBF**

- $R = \text{CorPP} / \text{CorBF}$

*Effect of severe aortic stenosis on myocardial O<sub>2</sub> supply and demand: PAST QUESTION*

**Aortic stenosis** =  $\downarrow$  cross sectional area of the valve + immobile valve leaflets

- chronic narrow LV outflow tract  $\rightarrow \uparrow$ mean pressure gradient across the valve to maintain flow + compensatory LV hypertrophy
- $\rightarrow$  relative ischaemia of LV myocardium, angina, arrhythmias, LV failure
- Severity grading:

| Severity | Valve area         | Mean gradient      |
|----------|--------------------|--------------------|
| Mild     | $>1.5\text{cm}^2$  | $<25\text{mmHg}$   |
| Moderate | $1-1.5\text{cm}^2$ | $15-50\text{mmHg}$ |
| Severe   | $<1\text{cm}^2$    | $>50\text{mmHg}$   |
| Critical | $<0.5\text{cm}^2$  | $>80\text{mmHg}$   |

**Myocardial O<sub>2</sub> supply**

- myocardium supplied by coronary circulation
- resting CorBF = 250ml/min (5% CO)
- high O<sub>2</sub> ER ~70%  $\rightarrow$  therefore dependent on CorBF for O<sub>2</sub>
- CorPP = driving pressure for coronary circulation
  - $\text{CorPP} = \text{ADP} - (\text{LVDP} / \text{RAP})$ 
    - ADP: aortic diastolic pressure
    - LVDP: LV diastolic pressure
    - RAP: R atrial pressure
  - LVDP and RAP  $\ll$  ADP  $\rightarrow$  therefore CPP  $\sim$  ADP
- ~80% CorBF + O<sub>2</sub> supply occurs during diastole
- **Severe AS – effect on myocardial O<sub>2</sub> supply**
  - **ventricular hypertrophy**  $\rightarrow \uparrow$ muscle mass
    - $\downarrow$ supply due to  $\downarrow$ calibre of coronary artery branches within myocardium  $\rightarrow \uparrow$ resistance to flow +  $\downarrow$ blood flow
    - dynamic compression of coronary arteries  $\rightarrow \downarrow$ lateral flow
  - **$\uparrow$ LV pressure during systole** (due to  $\uparrow$ afterload 2o narrow outlet)
  - **compensatory  $\uparrow$ HR**
    - Severe AS  $\rightarrow \downarrow$ CO +  $\downarrow$ MAP  $\rightarrow$  compensatory SY stimulation  $\rightarrow \uparrow$ HR  $\rightarrow \downarrow$ diastole:systole ratio  $\rightarrow \downarrow$ CorBF
  - **$\downarrow$ aortic root pressure**
  - **$\downarrow$ lateral flow**
    - $\uparrow$ flow velocity  $\rightarrow$  large kinetic energy  $\rightarrow \downarrow$ lateral pressure  $\rightarrow \downarrow$ coronary blood flow +  $\downarrow$ O<sub>2</sub> supply to myocardium

**Myocardial O<sub>2</sub> demand**

- amount of O<sub>2</sub> consumed by myocardium is determined by amount + type of activity undertaken
  - Dependent on: Ventricular wall tension (LaPlace); HR
- **Severe AS – effect on myocardial O<sub>2</sub> demand**
  - **ventricular hypertrophy**:  $\downarrow$ wall stress  $\rightarrow \downarrow$ O<sub>2</sub> demand
  - **ventricular dilation**: decompensation  $\rightarrow$  LV dilation + failure  $\rightarrow \uparrow$ LV radius  $\rightarrow \uparrow$ wall stress  $\rightarrow \uparrow$ O<sub>2</sub> demand
  - **ventricular pressure**:  $\uparrow$ afterload  $\rightarrow \uparrow$ ventricular pressure to maintain CO  $\rightarrow \uparrow$ wall stress  $\rightarrow \uparrow$ O<sub>2</sub> demand

Overall:

- $\downarrow$ CorBF  $\rightarrow \downarrow$ myocardial O<sub>2</sub> supply +  $\uparrow$ myocardial O<sub>2</sub> demands

Discuss the control of blood pressure and the distribution of blood volume and flow throughout the cardiovascular system including:

*The factors determining systemic blood pressure and its regulation and control*

**MAP = CO x SVR**

- maintained within narrow limits:
  - Fast, neurally mediated baroreceptor mechanism
  - Slower, hormonally regulated RAAS
- Achieved by:
  - Sensors: baroreceptors
  - Control centre: brainstem nuclei (vasomotor centre), medulla, hypothalamus
  - Effectors: SNS/ PNS efferents; RAAS

**Short term regulation: Baroreceptor reflex**

- afferent nerve cells (stretch Rs) in carotid arteries + aortic arch
- Fast, neural –ve feedback system; minutely regulation of arterial BP
- **Stimulus**: distension  $\rightarrow \uparrow$ intraluminal pressure  $\rightarrow \uparrow$ frequency of impulses discharged
- **Control centre**: send info to vasomotor centre (NTS) of medulla via CNX and CNIX
- **Effectors**: vasomotor centre: set point ~100mmHg  $\rightarrow$  modify PSY (via CVLM) and SY (via RVLM)
  - Venous constriction  $\rightarrow \uparrow$ VR +  $\uparrow$ preload  $\rightarrow \uparrow$ CO
  - $\uparrow$ HR,  $\uparrow$ contractility
  - vasoconstriction of arterioles  $\rightarrow \uparrow$ TPR
- 2 types of baroreceptor:

|               | Location                     | Stimulus                         | MoA                                                                                                                                                                                                                                                                                                                        |
|---------------|------------------------------|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| High pressure | Aortic arch<br>Carotid sinus | $\Delta$ BP by degree of stretch | $\uparrow$ MAP $\rightarrow \uparrow$ intraluminal P $\rightarrow \uparrow$ rate of firing CNX (aortic arch) CNIX (carotid) $\rightarrow$ inhibit vasomotor centre $\rightarrow \downarrow$ SY activity $\rightarrow \uparrow$ excitation cardio inhibi centre $\rightarrow \uparrow$ VA tone $\rightarrow \downarrow$ HR, |

Low pressure (cardiopul) RA + great veins  $\Delta\text{vol} \rightarrow \text{stretch}$

contractility, SV;  $\downarrow\text{SVR}$  (vaso + venodilation)  
 progressive stimulation  $>\text{MAP}60$ : max effect 180mmHg  
 $\uparrow\text{vol} (\uparrow\text{CVP}) \rightarrow \text{CNX to medulla} \rightarrow \uparrow\text{PNS}, \downarrow\text{SNS} \rightarrow \text{inhibitory to heart} \rightarrow \downarrow\text{HR}/$   
 contractility/ SV/ CO  
 Also:  $\downarrow\text{ADH}, \downarrow\text{thirst}, \uparrow\text{ANP}$

**Intermediate term: RAAS**

- slow hormonal system
- long term BP regulation via adjustment of blood vol
- **Stimulus:**
  - o Baroreceptors: carotid/ aortic/ pulmonary + intrarenal
  - o  $\downarrow$ renal perfusion sensed by juxtaglomerular cells (JGA)
- **Control centre:** vasomotor centre
- **Effectors:** renin
  - o Secreted from granule cells into interstitium + afferent arteriole lumen.
  - o acts on angiotensinogen to produce ATI  $\rightarrow \text{ACE} \rightarrow \text{ATII}$
  - o Regulators:
    - o **Neural signals:**
      1.  $\downarrow\text{BP} \rightarrow \uparrow$ renal SY nerve activity  $\rightarrow$  activates B1 adrenergic receptors on granular cells of afferent arteriole  $\rightarrow$  stimulates renin secretion via cAMP protein kinase A dependent process
    - o **afferent arteriolar pressure**
      1. granular cells also act as intrarenal baroreceptors
      2. deform in response to  $\Delta$ afferent arteriolar pressure (reflection of arterial BP)
      3.  $\downarrow$ pressure  $\rightarrow \uparrow$ renin production
    - o **NaCl at macula densa cells** of JGA + delivered to DCT
      1.  $\uparrow\text{Na}$  delivery  $\rightarrow \uparrow$ uptake of NaCl by cells  $\rightarrow$  osmotic swelling  $\rightarrow$  release of NT *inhibit renin release*
      2. NB does not directly regulate BP, but contributes to regulation of renin secretion
  - o Source of angiotensinogen = liver
  - o ACE is expressed on luminal surface of endothelial cells of vasculature – e.g. lungs; converts ATI to ATII
  - o **ATII**
    - o Most important in control of Na excretion + BP
    - o Affects BP directly as vasoconstrictor  $\rightarrow \uparrow\text{PVR}$  + indirectly via regulation of renal Na excretion
    - o –ve feedback to inhibit renin production by acting directly on granular cells (interacting with AT1 receptors on granular cells to  $\uparrow$ intracellular  $\text{Ca}^{2+}$  concentration  $\rightarrow$  inhibits renin production)

**Long term control: aldosterone regulation of Na balance****Effectors**

1. **Aldosterone**
  - a. Vital in correction of prolonged  $\downarrow\text{BP}$
  - b. Primary effect:  $\uparrow\text{Na}$  reabsorption in CT and CD by principal cells (2% of total filtered  $\text{Na}^+$ )
  - c. MOA:
    - i. aldosterone enters principal cells  $\rightarrow$  interacts with cytosolic aldosterone receptors  $\rightarrow$
    - ii. aldosterone bound receptors interact with nuclear DNA to promote gene expression  $\rightarrow$  translation of specific proteins  $\rightarrow$
    - iii.  $\uparrow$ activity or # of luminal  $\text{Na}^+$  channels + basolateral membrane Na-K-ATPase pumps  $\rightarrow \uparrow$ reabsorption of  $\text{Na}^+$
  - d. Control of aldosterone secretion
    - i. Inputs to adrenal gland regulate secretion
      1. **[ATII]**  $\rightarrow$  determined by **plasma [renin]**  $\rightarrow$  determined by intrarenal baroreceptors, macula densa, renal SY nerves
      2.  **$\uparrow$ plasma[K<sup>+</sup>]**

**Summary of system:**

- $\downarrow\text{BP} \rightarrow$  rapid short term baroreceptor mediated vascular response  $\rightarrow$  intermediate term renal mediated release of renin + production of ATII  $\rightarrow$  reinforces the initial short term vascular response + stimulates adrenal cortex to produce aldosterone

**Mean arterial pressure**

- $\text{MAP} = \text{Pd} + (\text{Ps} - \text{Pd}) / 3$
- MAP depends on 2 physical factors:
  - o mean blood volume in arterial system. Depends on:
    - rate of inflow into arteries from heart (CO)
    - rate of outflow from the arteries through the resistance vessels (peripheral runoff)
  - o arterial compliance
    - ratio of blood volume to mean blood pressure

**Arterial pulse pressure**

- pulse pressure =  $\text{SBP} - \text{DBP}$
- principally a function of SV (determines the change in arterial blood vol during ventricular systole)

*Total peripheral resistance and factors affecting it***Regional circulations**

- Flow = pressure change/ resistance
- The % of each organ blood flow is dependent on the organ vascular resistance
- Majority of resistance in systemic system results from arterioles – state of contraction and relaxation of smooth muscle cells of arterioles which determines distribution of blood to organs
- **1. Extrinsic control**
  - o Flow = pressure/ resistance. Important factors = TPR, CO, circulating vol
  - o **SYNS** – controls vascular tone, HR, contractility
  - o **PSYNS** – control sHR and vasodilation
  - o Extrinsic **hormonal** control: RAAS, ANP, ADH
- **2. Intrinsic control**
  - o **Autoregulation**
    - Ability of an organ to maintain relatively constant blood flow across variations in perfusion pressure
    - flow = pressure/ resistance → as the P changes, the R also changes to maintain flow
    - Outside limits of autoregulation: flow = dependent on driving pressure
    - Kidneys, brain, heart
  - o Autoregulation is dependent on 2 mechanisms:
    - **1. Pressure autoregulation:** myogenic stretch response to ↑ and ↓ in pressure → vasoconstriction, and vasodilation
    - **2. Metabolic or vasoactive autoregulation:** direct action of locally derived metabolites and vasoactive substances e.g. platelets release thromboxane A<sub>2</sub> → constriction in damage

NB: although arterioles have greater total cross sectional area than the large vessels, their smaller average radius more than outweighs this. In capillaries the situation is reversed, mean radius being far smaller again, but the total number of vessels in parallel making it a low resistance section of the circulation

- Peripheral resistance is largely maintained by SY tone, maintaining a basal level of vasoconstriction in vascular beds in skeletal muscle and skin
  - o SY tone → vasoconstriction of arterioles via alpha receptors
- Skeletal muscle constitutes the largest single vascular bed and the major determinant of total peripheral resistance

*Describe the relationship between vascular tone and tissue oxygenation*

*Describe the factors that influence the rate of blood flow through a capillary bed*

- direct relationship between tissue oxygenation and vascular tone
  - o ↓O<sub>2</sub> = ↓vascular tone
  - o blood flow is coupled to local tissue metabolic requirements
- Autoregulation = tissues ability to regulate its own blood supply so that it receives the flow it requires for its functions
  - o Role of autoregulation in most tissues = to maintain delivery of O<sub>2</sub> and nutrients to the tissues at a normal levels + remove waste products despite Δarterial pressure
  - o Metabolic autoregulation
    - ↑metabolism or ↓O<sub>2</sub> available to tissues → release of vasoactive substances that cause vasodilation
    - substances include: NO, adenosine, ↑CO<sub>2</sub>, ↑K<sup>+</sup>, ↑Mg<sup>2+</sup>, ↑H<sup>+</sup>
- E.g. reactive hyperaemia
- E.g. cerebral circulation

*Describe the vasoactive substances released by the endothelium. Explain the role they play in regulating blood flow through the peripheral circulation: PAST QUESTION*

**Vasoactive substances**

- primarily released to effect local arteriolar smooth muscle tone → match regional blood supply to metabolic demand

**Vasodilators**

- **NO (nitric oxide)**
  - o Produce by NO synthetase activity on L-arginine
  - o Release triggered by:
    - Shear stress
    - ↑NTs: Ach, bradykinin, 5-HT, substance P, histamine
    - metabolic activity of tissue: ↓PaO<sub>2</sub>, ↑pCO<sub>2</sub>, ↑[H<sup>+</sup>], ↑temp, ↑lactate acid, ↑pyruvate, ↓ATP, ↑ADP, ↑AMP, ↑adenosine
    - electrolytes: ↑[K<sup>+</sup>]
- **Prostacycline (PGI<sub>2</sub>)**
  - o Derived from COX-1 activity on arachadonic acid
  - o Triggered by: pulsatile flow ?shear stress
  - o Effect site: ↓arteriolar smooth muscle tone via activation of adenylyl cyclase → ↑cAMP → ↓MLKC activity → vasodilation, inhibition of platelet aggregation (↓Ca<sup>2+</sup> availability)

**Vasoconstrictors**

- **Endothelin**
  - o Most potent of all vasoconstrictors
  - o Acts locally + systemically
  - o 3 types: ET1 (endothelium, brain, kidney); ET2 (GIT); ET3 (adrenals)
  - o Trigger unknown
  - o Effect site: ↑arteriolar smooth muscle tone via activation of G proteins → vasoconstriction

**Others (non vasoactive)**

- tissue factor
- heparin sulphate: ↑ATIII activity
- thrombomodulin: binds + inactivates thrombin; activates protein C/S → ↑tPA + ↑fibrinogen

**Regional circulations**

*The relationship between organ blood flow and demand and the role of autoregulation*

| Distribution of blood volume | Blood flow distribution at rest |     |        |             |
|------------------------------|---------------------------------|-----|--------|-------------|
|                              | Tissue                          | %CO | ml/min | ml/min/100g |
| - Pulmonary circulation 9%   | Brain                           | 14  | 700    | 50          |
| - Heart 7%                   | Heart                           | 4   | 200    | 70          |
| - Arteries 13%               | Bronchi                         | 2   | 100    | 25          |
| - Arterioles 2%              |                                 |     |        |             |

|                  |         |     |      |                 |
|------------------|---------|-----|------|-----------------|
| - Capillaries 5% | Kidneys | 22  | 1100 | 360             |
| - Veins 64%      | Adrenal | 0.5 | 25   | 300             |
|                  | Liver   | 27  | 1350 | 95 (75% portal) |
|                  | Muscle  | 15  | 750  | 4               |
|                  | Bone    | 5   | 250  | 3               |
|                  | Skin    | 6   | 300  | 3               |

### Clinically significant features of the coronary, cerebral, skin, muscle, renal, hepatic and splanchnic circulations

#### Cerebral and spinal cord circulation

- Blood supply to brain: internal carotid arteries (2/3) and vertebral arteries (1/3)
- At rest: 750ml/min of blood flow = 15% total CO
- Cerebral blood flow = 50ml/100g/min
  - o White matter: 20ml/100g/min
  - o Grey matter: 70ml/100g/min (metabolically more active)
- O<sub>2</sub> consumption of brain: 3ml O<sub>2</sub>/100g/min = 50ml O<sub>2</sub> = 20% total consumption
  - o Requires large amount of energy; limited capacity for anaerobic metabolism → absence of O<sub>2</sub> irreversible cell damage
- **CBF = CPP / CVR**
  - o CPP = MAP – ICP
  - o CVR: vasodilation (→ ↑blood vol → ↑ICP) → ↓CPP e.g. vasoconstriction
  - o Autoregulated between MAP 50-150mmHg (reset in chronic HTN)
- Control
  - o **Autoregulation**
    - Myogenic stretch factors
    - Chemical factors:
      - [H<sup>+</sup>]
      - PCO<sub>2</sub> → linear relationship with CBF from 20-80mmHg.
        - o ↑PaCO<sub>2</sub> → vasodilation → ↑blood vol → ↑ICP → ↓
        - o ↓PaCO<sub>2</sub> → vasoconstriction → ↓blood vol → ↓ICP
      - PaO<sub>2</sub> <50mmHg → ↑CBF
    - ↑Cerebral metabolic rate → ↑CBF (e.g. pyrexia, seizures)
    - Local metabolic factors: adenosine, NO, H<sup>+</sup>
  - o **Extrinsic nerve and hormonal** control have little influence on CBF
    - SY: vasoconstriction; shift autoregulation curve to right in HTN
    - PSY: vasodilation
  - o Other
    - Blood viscosity: ↓viscosity → ↑flow (Hagen-Poiseuille's law)

Threshold values for cerebral ischaemia = CBF below which known neuronal physiological changes occur

- <50ml/100g/min → acidosis
- <40ml/100g/min → protein synthesis impaired
- <30ml/100g/min → oedema
- <20ml/100g/min → electrical function fails
- <10 ml/100g/min → cell death

#### Hepatic circulation

##### Blood supply to the liver

- Total hepatic blood flow: 1500ml/min = 60ml/100g/min = 30% CO
- Derived from:
  - o Hepatic artery
    - 25% of flow; 40% O<sub>2</sub> supply
    - 300-500ml/min; mean pressure 90-100mmHg
    - some autoregulation
  - o Portal vein
    - 75% of flow; 60% O<sub>2</sub> supply
    - 1000-1200ml/min; mean pressure 10mmHg
    - No autoregulation
    - Contains venous drainage from the bowel
- Hepatic triads: hepatic artery + portal vein + bile canaliculus
- Sinusoids:
  - o Consist of: portal arteriole + venule
  - o Forms low pressure microcirculation that optimizes exchange with hepatocytes
- Venous blood from the liver returns to the IVC through the R and L hepatic veins. A separate set of veins drain the caudate lobe of the liver

##### How is blood flow regulated?

- Arterial supply = regulated by intrinsic + extrinsic mechanisms
- portal venous flow = regulated by extrinsic factors only
- **Intrinsic**
  - o Myogenic autoregulation
    - If hepatic arterial pressure ↓s → ↓hepatic arterial resistance → maintains flow
    - Portal vein has no autoregulation → therefore flow is proportional to the pressure gradient and resistance
  - o Hepatic arterial buffer response
    - Compensatory Δhepatic artery:
      - ↓flow portal vein → compensatory ↓resistance in hepatic artery → arterial blood flow ↑s
      - Adenosine responsible: ↓portal flow → ↑[adenosine] around hepatic triads → arterial vasodilation
      - NB: ↓flow hepatic artery → no portal vein dilation with ↑adenosine → little compensatory Δportal flow
- **Extrinsic**
  - o SYNS
    - Hepatic artery: contains a + b adrenoceptors
    - Portal vein: a receptors

- Constricts sinusoidal capacitance vessels → mobilises blood reservoirs → important in stress response
- ↓splanchnic blood flow → ↓portal venous flow / ↓hepatic artery flow
- **Circulating factors:**
  - Angiotensin
  - Endothelin
  - Vasopressin: constricts hepatic vasculature → ↓hepatic blood flow
  - Glucagon: vasodilation of hepatic artery + portal vein → ↑hepatic blood flow
  - Histamine
- **Right heart function**
  - RHF → ↑CVP → hepatic congestion as transhepatic gradient falls

### Splanchnic circulation

#### Renal

- 1250ml of CO = 25%
- Anatomically: blood derived from coeliac, SMA, IMA
- Partially in parallel (gastric, spleen, pancreas, small intestine, colonic) and partially in series – due to liver
- Important reservoir – pooling in capacitance vessels of mesentery, spleen, liver
- Control
  - Extrinsic: SYNS → ↑venous constriction → ↑circulating blood vol + ↑resistance of arterioles → diverts blood away from digestive system
  - Intrinsic: present in hepatic artery; metabolic control

### Renal circulation

#### Renal

- Rest: 1250ml/min = 25% blood flow
- Autoregulation/ intrinsic control
  - 75-170mmHg
  - Myogenic stretch mechanisms
  - Tubuloglomerular feedback via afferent arteriole constriction: macula densa → releases adenosine if RPP↑s
- Extrinsic control
  - SY innervation
  - RAAS
  - ADH

### Uteroplacental

Draw aortic root and radial artery pressure waveforms on the same axis. Explain the differences: PAST QUESTION

#### Aortic root waveform:

- ↑ pressure on opening of aortic valve during systole
- reaches peak pressure 120mmHg (normal adult)
- closure of aortic valve results in incisura on the 1<sup>st</sup> part of the pressure descent
- gradual ↓pressure due to Windkessel effect: elastic potential energy stretching the aorta during systole is converted back into kinetic energy to propel blood during diastole

#### Radial artery waveform

- Measured distal to the aorta → delay in arrival of impulse (despite fact that pressure waveform travels faster than blood)
- Higher peak pressure (taller) → due to resonance and reflection (summation of waveforms)
- ↑velocity of higher peak (narrowest peak)
- ↓compliance of arterial walls (loss of windkessel effect) → steeper upslope
- no incisura (notch) high pressure component damped out
- diastolic hump present → combination of reflection, resonance

#### Differences with age:

- ↓myocardial function: aortic = slower rise to peak pressure
- ↑stiffness of vessels:
  - Aortic: ↑peak pressure → lead to progressively less distortion of waveform distally
  - Radial: ↑peak pressure
- All changes ↓ in elderly due to ↓arterial compliance

Discuss the factors that influence the rate of blood flow through a capillary bed

- direct relationship between tissue oxygenation + vascular tone (↓O<sub>2</sub> = ↓vascular tone)
- blood flow is coupled to local tissue metabolic requirements
- autoregulation = tissues ability to regulate its own blood supply to maintain DO<sub>2</sub> + nutrients despite changes in arterial pressure
  - myogenic mechanism
  - metabolic mechanism
    - ↑rate of metabolism / ↓O<sub>2</sub> available → release of vasoactive substances → vasodilation
    - e.g.: substance P/ NO/ adenosine/ ↑CO<sub>2</sub>/ ↑K<sup>+</sup>/ ↑Mg<sup>2+</sup>/ ↑H<sup>+</sup>

The skin, kidneys, carotid bodies are examples of where specific organ blood flow is far in excess of that organs metabolic requirements. For each example, explain what the physiological role of the high organ blood flow is, why this high flow is an advantage to the person and a brief description of the mechanisms involved: PAST QUESTION

#### Physiological role of high organ blood flow

| Organ   | Basal flow                    | %CO | Physiological role                                                            | Mechanism involved                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------|-------------------------------|-----|-------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### The essential features of the microcirculation including fluid exchange and its control

#### Physiological processes involved in the development of interstitial oedema: PAST QUESTION

- capillaries contain semipermeable membranes to allow the movement of fluid + solutes
- normally impermeable to large proteins
- plasma ultrafiltrate is filtered by bulk flow through the capillary wall by the action of opposing hydrostatic + oncotic pressures (Starling forces)

#### Starlings forces

- capillary hydrostatic pressure ( $P_c$ )**
  - pressure exerted on the capillary by a column of whole blood within it
  - pressure pushing fluid out of a capillary
  - venous 15mmHg → arterial 25mmHg
- Interstitial hydrostatic pressure ( $P_i$ )**
  - Pressure exerted on the capillary by the fluid in the interstitial space
  - Pressure pushing fluid into capillary
  - Usually 0mmHg
- Capillary oncotic pressure ( $\pi_c$ )**
  - Pressure that would be required to prevent the movement of water across a semipermeable membrane due to the osmotic effect of large plasma proteins
  - I.e. pressure pulling fluid into capillary
- Interstitial osmotic pressure ( $\pi_i$ )**
  - Pressure that would be required to prevent the movement of water across a semipermeable membrane due to effect of interstitial fluid particles
  - I.e. pressure pulling fluid out of capillary
- Net filtration pressure (NFP) / fluid flux = outward forces – inward forces
  - $NFP = K_f [(P_c - P_i) - \sigma(\pi_i - \pi_c)]$ 
    - $K_f$  = filtration coefficient → reflects capillary permeability
    - $\sigma$  = reflection coefficient → leakiness of membrane to protein

| Parameters | Arterial (mmHg) | Venous (mmHg) |
|------------|-----------------|---------------|
| $P_c$      | 30              | 10            |
| $P_i$      | -6              | -6            |
| $\pi_c$    | 25              | 25            |
| $\pi_i$    | 5               | 5             |
| Net        | +16 (out)       | -4 (in)       |

#### Interstitial oedema

- Occurs when there is accumulation of interstitial fluid
- As oedema develops → changes in the interstitial Starling variables limit the formation of oedema
- Occurs with:
  - Imbalance of Starling Forces
    - $\uparrow P_c$  → e.g.  $\uparrow$ arterial pressure,  $\uparrow$ precapillary sphincter, venous obstruction → fluid overload, CCF
    - $\downarrow P_i$  → rare e.g. -ve pressure pulmonary oedema
    - $\uparrow \pi_i$  → e.g. low plasma protein → burns, plasma leak
    - $\downarrow \pi_c$  →  $\downarrow$ plasma protein e.g. liver failure, nephrotic syndrome, malnutrition
    - $\uparrow NFP$  → greater driving force of fluid out of capillary → interstitial oedema
  - impaired lymphatic drainage e.g. LN removal
  - $\uparrow K_f$  → infection/ inflammation →  $\uparrow$ leakiness of capillaries 2o cytokine production

#### Explain the local effects of a decrease in plasma colloid osmotic pressure in a skeletal muscle capillary bed: PAST QUESTION

See above for explanation of Starlings Forces

#### $\downarrow$ plasma colloid osmotic pressure

- Occurs with
  - $\downarrow$ protein synthesis: end stage liver failure
  - $\uparrow$ protein loss: protein losing nephropathy
- Effect: causes a  $\downarrow$ osmotic pressure exerted
  - All other forces remain equal →  $\uparrow$ bulk flow into interstitium: once this overwhelms the drainage capacity of lymphatics system → results in interstitial oedema
  - Incidentally, the movement of fluid into interstitium → results in  $\downarrow P_c$  which will favour absorption at the venous end
- Consequences:
  - $\uparrow$ diffusion distance for: O<sub>2</sub>, nutrients into mitochondria, waste products out of cells
  - $\downarrow$ efficiency of excitation/ contraction coupling:  $\downarrow$ overlap of fibres
  - $\uparrow P_i$ :  $\downarrow$ movement of solutes/ fluid → can lead to compression of capillary

*Describe the waveforms and pressures that are seen in each anatomical location during insertion of a pulmonary artery catheter.*

*What factors may increase these pressures? PAST QUESTION*

Pulmonary artery catheter 110cm long catheter with 4 internal lumens used for:

- CVP monitoring
- Calculation of CO, mixed venous O<sub>2</sub> saturations, PA pressures, wedge pressures

#### Waveform features

- CVP and RA
  - o Standard CVP waveform:
    - A wave: atrial contraction
    - C wave: bulging of tricuspid with ventricular contraction
    - X descent
    - V wave: passive filling of RA
    - Y descent
  - o Normal CVP/ RAP: 0-8mmHg
- RV
  - o Standard pressures: systolic 15-30mmHg; diastolic 0mmHg
  - o EDP should be the same as RA
  - o No dirotic notch in RV pressure waveform + baseline upsloping due to pressure transmission
- Pulmonary artery
  - o Standard systolic pressures are same as for RV (15-30mmHg); diastolic pressures 8-15mmHg
  - o Descending systolic portion shows dirotic notch related to pulmonary valve closure
  - o Diastolic portion downsloping due to runoff into the LA
- Wedge pressure
  - o Reflects LAP with shape characteristics similar to RA trace but with higher pressure values (5-15mmHg)
  - o Trace less clear due to damped transmission through capillary vessels

Conventionally the 'wedge' value or occlusion pressure is measured at the end of expiration.

#### Factors that ↑ pressure

- CVP/ RAP: ↑preload/ filling; ↓CO; TR
- RVP: pulmonary stenosis; LVF
- PAP (i.e. pulmonary HTN): idiopathic, pulmonary thromboembolism, LVF, lung disease, CT disease
- PCWP: LVF

### Cardiovascular responses to: changes in posture/ exercise/ valsalva/ PPV + PEEP/ pneumoperitoneum/ haemorrhage + hypovolaemia/ surgery + trauma

#### Cardiac reflexes:

- The cardiac reflexes are a series of reflex pathways which exist between cardiovascular and CNS and contribute to maintenance of homeostasis
- Receptors are located in atria, ventricles, pericardium, cardiac, and great vessels
- Afferent signals: VA nerve (other CN depending on reflex) → to nucleus of the solitary tract in cardiovasc centre of the medulla
- Efferent signals: VA

#### Important reflexes:

| Reflex                                    | Location of receptors                                                                                                                                     | Stimulus                                                           | Travel via                                                                  | Response/ effect                                                          |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------|-----------------------------------------------------------------------------|---------------------------------------------------------------------------|
| Baroreceptor reflex                       | Most important<br><br>Second to second control of BP via circumferential and longitudinal stretch receptors located in <b>carotid sinus + aortic arch</b> | Stretch changes in <b>MAP</b> : 50-200mmHg (set point MAP 100mmHg) | Afferent signals: travel via C fibres in <b>glossopharyngeal + VA nerve</b> | alteration of autonomic activity (↓BP → inhibit PSY → ↑tonic SY activity) |
| Bainbridge reflex "atrial stretch reflex" | Stretch receptors in wall of RA and cavoatrial junction                                                                                                   | Fire in response to ↑distending pressures                          | Vagus                                                                       | ↑SNS activity to SA node → tachycardia → aim to ↓blood vol back to normal |
| Bezold-Jarisch reflex                     | Chemo + mechanoreceptors in LV                                                                                                                            | Sense noxious stimuli                                              | Vagus                                                                       | hypotension + bradycardia + coronary artery vasodilation                  |
| Chemoreceptor reflex                      | Carotid + aortic bodies                                                                                                                                   | Sense changes in PaO <sub>2</sub> (<50mmHg) and pH                 | Carotid: glossopharyngeal<br>Aortic bodies: vagus                           | Tachycardia/ HTN                                                          |
| Cushing reflex                            | ↑ICP                                                                                                                                                      | ↑ICP → ischaemia of vasomotor centre                               |                                                                             | Baroreceptors sense ↑arterial tension<br>Reflex bradycardia               |

#### Changes in posture

**Describe the compensatory mechanisms in a fit person moving from the supine to the standing position**

##### Effects on moving supine to standing

- ↑hydrostatic pressure 2° to gravity (circulation = column of fluid)
- ↑venous pooling → ↓VR → ↓SV → ↓CO → ↓MAP
- ↑vertical distance from heart to brain
  - o ↓MAP at carotid sinus ~22mmHg
  - o CPP = MAP - CVR (ICP) therefore CPP ↓s ~20% initially

#### Compensatory mechanisms

Aim: maintain MAP + maintain CBF

- **Maintenance of MAP: MAP = HR x SV x TPR**

- **Baroreceptor reflex** (rapid response)
  - $\downarrow$ VR  $\rightarrow$   $\downarrow$ MAP  $\rightarrow$  detected as  $\downarrow$ stretch by high pressure baroreceptors (carotid sinus, aortic arch)  $\rightarrow$   $\downarrow$ firing receptors  $\rightarrow$  removal of inhibition from vasoconstrictor centre
  - $\uparrow$ SNS stimulation ( $\downarrow$ PNS output):
    - $\uparrow$ HR,  $\uparrow$ SV,  $\uparrow$ contractility  $\rightarrow$   $\uparrow$ CO
    - vasoconstriction  $\rightarrow$   $\uparrow$ TPR /  $\uparrow$ afterload
    - venoconstriction  $\rightarrow$   $\downarrow$ venous capacitance + mobilisation of venous reservoir
  - $\uparrow$ VR
    - venoconstriction
    - Muscle pump (contraction lower limb mm)
    - thoracic pump (with respiration)
    - Venous valves
- net effect = return MAP to normal in few seconds
- **Maintenance of CBF:  $CBF = CPP / CVR$**   $\rightarrow$  Where  $CPP = MAP - CVP$  (ICP)
- Factors affecting **CPP**
  - MAP
  - $\downarrow$ CVP: upright posture: drainage of outlet vessels to R heart
  - Monroe-Kelly doctrine :  $\downarrow$ CVP on standing  $\rightarrow$   $\downarrow$ ICP  $\rightarrow$   $\uparrow$ CPP and  $\uparrow$ CBF
- Factors affecting **CVR**
  - **Metabolic autoregulation**
    - Local rapid redistribution of regional blood flow within brain based on metabolic demand
    - Via local release of vasoactive substances
  - **Pressure autoregulation (myogenic mechanism)**
    - $\downarrow$ MAP  $\rightarrow$   $\downarrow$ CPP  $\rightarrow$   $\downarrow$ stretch on arterioles  $\rightarrow$  reflex  $\downarrow$ resting tone of smooth mm  $\rightarrow$   $\downarrow$ CVR

**Overall:**

- on standing: MAP/ CBF  $\downarrow$ 20% for few seconds  $\rightarrow$  reflexes rapidly restore MAP/ CBF
- failure to correct CBF  $\rightarrow$  faint  $\rightarrow$   $\downarrow$ vertical distance between heart and brain, remove hydrostatic effect of gravity on MAP  $\rightarrow$   $\uparrow$ CPP

**Exercise****Cardiovascular response to exercise**

- heart = demand pump: local tissue control of vascular beds determines amount of blood required to meet local metabolic demands
- Exercise can  $\uparrow$ CO by 5x
- Blood flow to skeletal muscle: 1L/min at rest (20% CO);  $\uparrow$  to  $>20$ L/min during heavy exercise (80% CO)

**Local control/ effects**

Local factors are 1° determinant of skeletal muscle blood flow

1. **Metabolic control (primary mechanism)**
  - $\uparrow$ metabolic demand of skeletal muscle:  $\uparrow$ O<sub>2</sub>, glucose, FFA, ketones (substrates for ATP production)
  - $\uparrow$ metabolite production:  $\downarrow$ pH,  $\downarrow$ pO<sub>2</sub>,  $\uparrow$ pCO<sub>2</sub>,  $\uparrow$ K<sup>+</sup>,  $\uparrow$ adenosine
  - effect: reflex dilation of capillary beds  $\rightarrow$   $\downarrow$ TPR
2. **Vasoactive substances**
  - N<sub>2</sub>O produced by exercising muscle  $\rightarrow$  dilation of capillary beds

**Systemic effects**

1. **Catecholamine production**
  - Ad/ Nad production from adrenals: stimulates heart B<sub>1</sub> Rs + vascular  $\alpha$ <sub>2</sub> Rs
2. **SNS activation  $\rightarrow$   $\uparrow$ CO:**
  - $\uparrow$ VR: arterial vasodilation ( $\downarrow$ TPR); venoconstriction; blood shift/ muscle pump
  - $\uparrow$ HR:  $\downarrow$ VA tone,  $\uparrow$ SV drive;  $\uparrow$ linearly with exercise
  - $\uparrow$ SV:  $\uparrow$ with intensity of exercise by 10-35%; beyond this SV  $\downarrow$  as HR  $>200$  due to  $\downarrow$ diastolic filling time
  - $\uparrow$ BP + widened pulse pressure
  - $\downarrow$ PVR: local metabolites in muscle
3. **O<sub>2</sub> carriage**
  - Bohr effect
    - R shift OHDC in response to  $\uparrow$ pCO<sub>2</sub>,  $\downarrow$ pO<sub>2</sub>,  $\uparrow$ H<sup>+</sup>,  $\uparrow$ 2,3DPG production  $\rightarrow$   $\downarrow$ affinity of Hb for O<sub>2</sub>
    - Improved loading of O<sub>2</sub> at the lung capillary + offloading at active tissues
4. **Changes to regional blood flow**
  - $\uparrow$ flow to skin
    - dilation of cutaneous capillary beds:  $\uparrow$ heat loss through skin
    - $\uparrow$ apocrine sweat gland activity  $\rightarrow$   $\uparrow$ heat loss through evaporation
  - redirection of splanchnic, liver, GIT blood flow via SNS activation to  $\uparrow$ availability for muscle +  $\uparrow$ catecholamine production from adrenals

**Isometric I. isotonic exercise**

- Isometric: sustained contraction of muscle  $\rightarrow$  compression of capillary beds  $\rightarrow$   $\uparrow$ TPR due to  $\uparrow$ resistance in muscle beds
- Isotonic: contraction + relaxation of muscle  $\rightarrow$  overall  $\downarrow$ TPR due to dilation of capillary beds

*Valsalva manoeuvre*

- action of forced expiration against a closed glottis after full inspiration
  - o  $P_{AW}$  40mmHg should be achieved + held for 10 seconds
  - o  $\uparrow$ intraabdo, intracranial, mouth, middle ear pressure

*Uses:*

- test of autonomic function
- Termination of SVT (due to  $\uparrow$ VA tone during 4<sup>th</sup> phase)
- Clear middle ear content
- Recruitment
- HOCM murmur

*4 phases***1. phase 1: Squeeze**

- o  $\uparrow$ BP,  $\downarrow$ HR
  - $P_{AW}$   $\uparrow$  to 40cmH<sub>2</sub>O  $\rightarrow$   $\uparrow$ Pintrathoracic
  - $\uparrow$ SBP + DBP due to: compression of aorta +  $\uparrow$ LV preload due to eject
  - Reflexive  $\downarrow$ HR

**2. Phase II: ring out**

- o  $\downarrow$ BP,  $\uparrow$ HR
  - +ve Pintrathoracic maintained:  $\downarrow$ VR  $\rightarrow$   $\downarrow$ CO  $\rightarrow$   $\downarrow$ SBP + DBP
  - Carotid baroreceptors + SNS outflow:  $\uparrow$ HR +  $\uparrow$ SVR (peripheral vaso)
- o Pulse pressure narrow due to  $\downarrow$ CO ( $\downarrow$ SBP) + vasoconstriction ( $\uparrow$ DBP)

**3. Phase III: absorb (brief)**

- o  $\downarrow$ BP; no time for  $\Delta$ HR
  - Valsalva ceases:  $P_{AW}$  returns to 0cmH<sub>2</sub>O
  - $\downarrow$ PVR as alveolar vessels re-expand
  - SBP + DBP rapidly  $\downarrow$  due to:
    - $\downarrow$ PVR  $\rightarrow$   $\downarrow$ LV preload
    - Loss of high intrathoracic pressure compressing aorta

**4. Phase IV: overshoot**

- o  $\uparrow$ BP;  $\uparrow$ HR to normal
  - Baroreceptors respond to  $\downarrow$ BP by  $\downarrow$ afferent discharge/ inhibitory effect on pressor centre  $\rightarrow$  vasoconstriction +  $\uparrow$ VR
  - BP recovers rapidly as CO restored; overshoots because blood is delivered into vasoconstricted periphery
- o Overshoot sensed by baroreceptors  $\rightarrow$  reflex VA response  $\rightarrow$   $\downarrow$ HR + restores BP to normal

*Abnormal responses*

- Square waveform:
  - o CCF, constrictive pericarditis, cardiac tamponade, valvular heart disease  $\rightarrow$  when CVP markedly  $\uparrow$ ; BP remains  $\uparrow$  throughout + returns to previous level at end
- Autonomic dysfunction:
  - o BP  $\downarrow$ s + remains low until 28response28rict pressure released.
  - o  $\Delta$ HR + overshoot are absent
- IPPV or hypovolaemic patients:
  - o exaggerated  $\downarrow$ in BP

*Positive pressure ventilation and PEEP***Effects of IPPV on left ventricular output**

- IPPV:  $\uparrow$ mouth / airway pressure to inflate lungs; in exp phase, pressure released to preset pressure (PEEP) or ambient pressure

**LV output** = vol of blood flowing out of the LV per unit time

- Dependent on:
  - o LVEDV (preload):
    - related to degree of VR + stretch of LV mm fibres at end of diastole
    - dependent on HR + SV
  - o Afterload: sum of forces that oppose LV output i.e. ventricular wall tension during contraction
    - according to **Law of LaPace**:
      - wall tension = transmural pressure x radius / 2x wall thickness
      - transmural pressure = intracavity pressure – intrapleural pressure
  - o Contractility

**IPPV: inspiration i.e.**

- Inspiration =  $\uparrow$ ITP
  1. **Initially  $\uparrow$ LV output**
    - LVEDV: Initially pulmonary reservoir of blood mobilised 2°  $\uparrow$ ITP: transient  $\uparrow$ LA filling  $\rightarrow$   $\uparrow$ LV SV  $\rightarrow$   $\uparrow$ LV output  $\rightarrow$   $\uparrow$ CO
  2. **Then  $\downarrow$ LV output**
    - VR: As pressure  $\uparrow$ s: LV output  $\downarrow$ s as large systemic veins are compressed  $\rightarrow$   $\uparrow$ resistance to VR  $\rightarrow$   $\downarrow$ RV preload
    - RV outflow:  $\uparrow$ PVR  $\rightarrow$   $\uparrow$ RA afterload  $\rightarrow$  septum bulges into LV  $\rightarrow$   $\downarrow$ LV compliance + filling
  3. **Also a  $\downarrow$ afterload (LV outflow)**
    - IPPV  $\rightarrow$   $\uparrow$ ITP  $\rightarrow$   $\downarrow$ transmural pressure  $\rightarrow$   $\downarrow$ afterload
- **therefore:**
  - o Initial transient  $\uparrow$ in LV output  $\rightarrow$  followed by prolonged  $\downarrow$ LV output +  $\downarrow$ LV afterload
  - o In pts with impaired myocardial contractility  $\rightarrow$  IPPV may result in improved CO due to effect of  $\uparrow$ intrathoracic pressure on  $\downarrow$ afterload +  $\downarrow$ preload

**IPPV: expiration**

- Expiration =  $\downarrow$ ITP
  1. **Initially:**
    - $\downarrow$ intrathoracic pressure  $\rightarrow$   $\downarrow$ PVR  $\rightarrow$   $\uparrow$ capacitance  $\rightarrow$   $\uparrow$ pulmonary blood vol
    - $\downarrow$ LA return  $\rightarrow$   $\downarrow$ LVEDV  $\rightarrow$   $\downarrow$ SV  $\rightarrow$   $\downarrow$ CO
  2. **Then:**
    - $\uparrow$ R heart VR ( $\uparrow$ RV preload)  $\rightarrow$   $\downarrow$ RV afterload 2o  $\downarrow$ PVR  $\rightarrow$   $\uparrow$ LA preload +  $\uparrow$ CO

- NB: effect of ↓VVR on CO is exacerbated by hypovolaemia, PEEP, hypoxia, hypercapnoea, autonomic neuropathy, ↓SYNS drive

#### Factors affecting above:

- **baroreceptor reflex:**
  - ↓MAP → ↓stretch high pressure baroreceptors (carotid sinus, aortic arch) → ↓firing cells sensed by vasomotor centre → ↑SNS activity/ ↓PNS activity → ↑HR
  - ↑contractility, vaso/ veno constriction to maintain MAP
- **PEEP/ hypovolaemia**
  - Both exacerbate effect of IPPV
  - Maintains ↓VR
  - PEEP → ↑PVR
  - Leads to exaggerated loss ↓MAP as compensatory mechanism impaired
- Overall effect on CVS:
  - depends on: Age, cardiac function, volume state
  - Young people with normal function: IPPV tends to cause ↓CO and ↓BP
  - Elderly with impaired LV function: IPPV tends to have nil effect or improve CO + BP

#### Pneumoperitoneum

Pneumoperitoneum involves insufflating the abdomen with gas

- Most commonly used gas = CO<sub>2</sub>
  - Inexpensive
  - Inhibits combustion
  - Readily available
  - Rapidly absorbed + metabolised by the patient
- Used in laparoscopic surgery to aid exposure
- Intraabdominal pressure 10-12cm H<sub>2</sub>O
- Effects can be mechanical or biological 2o insufflated gas

#### Mechanical

- CVS
  - Venous pooling in legs
  - IVC compression → ↑RVR, ↓VR → ↓CO
  - ↑vascular resistance of intra-abdo organs → ↑SVR
- Regional effects
  - Venous stasis in legs → DVT
  - PCO<sub>2</sub> → vasodilation if vent not ↑
  - Arrhythmias: bradycardia 2o peritoneal manipulation
- Resp
  - ↓compliance
  - ↑intra-thoracic pressure on IPPV
- neuroendocrine
  - ↑ADH, catecholamines, renin, ATII
  - ↑SY tone
- Net result: ↓CO, ↑MAP → minimised by filling, head down position, α<sub>2</sub> agonists

#### Biological effect of insufflated gas

- Hypercarbia
  - Once absorbed: CO<sub>2</sub> + H<sub>2</sub>O → H<sub>2</sub>CO<sub>3</sub> → HCO<sub>3</sub> + H<sup>+</sup> → metabolic acidosis
  - Metabolic acidosis → myocardial depression, ↓CO, ↑PVR
  - Generally well tolerated; pts at ↑risk of complication: pulmonary HTN, CCF, sepsis, hypovolaemia, cardiomyopathy

#### Haemorrhage/ hypovolaemia

- Assessment of loss
  - <25% loss: ↑HR, BP normal, pulse pressure narrow; ↑CRT
  - 25-40% loss: ↑HR, ↓BP, ↑CRT, ↑RR, oliguria, altered mental state
  - >40% loss: shock; ↓HR, ↓BP, ↑RCT, ↑RR, anuria, coma → due to vagally mediated cardiac afferent C-fibre discharge caused by ventricular distortion + underfilling
- Loss of 1L of blood
  - Lose 40g albumin
  - 140mmol Na, 100mmol Cl, 4mmol K

#### Summary of physiological effects of haemorrhage

- ↓blood vol → ↓VR, ↓CO
- ↓arterial BP → activation of baroreceptor reflex
- ↑SY → ↑HR, peripheral vasoconstriction, viscera, kidneys
- ↑vasopressin → vasoconstriction, Na<sup>+</sup> H<sub>2</sub>O retention, thirst

#### Effect in more detail:

- **Haemodynamic:** ↓filling pressure, ↓SV, ↓CO, ↓MAP
- **Baroreceptor** (response max at MAP 60): ↓stimulation at carotid sinus and aortic receptors; ↓VA tone, ↑SY tone → ↑HR, ↑contractility, peripheral vasoconstriction → ↑SVR, ↑filling pressure, centralised blood volume
- **Chemoreceptor:**
  - Some augmentation of SY response below MAP 60
  - Hypoxia, hypercapnia, acidosis → stimulate carotid and aortic bodies → ↑SY tone, ↑resp drive → minor ↑in VR
- **Cerebral ischaemic response:** further augmentation of SY tone <MAP 40mmHg; also ↑CA tone (maladaptive)
- **Autoregulatory vascular response:** arteriolar constriction due to myogenic mechanism
- **Reabsorption of tissue fluids:**
  - ↓capillary hydrostatic pressure
  - Reversed starling forces: transfer of fluid from interstitium into circulation; up to 1l/hr
  - Transfer from ICF to interstitial fluid also occurs in response to cortisol
- **Endogenous vasoconstrictors**

- Adrenaline and noradrenaline: from adrenal medulla and SY nerves → responsible for acute SY response
- ADH: rapid secretion from posterior pituitary in response to hypotension; vasoconstrictor, ↑water reabsorption from collecting ducts; ↑expression of vWF and VIII
- Renin: catalyzes conversion of angiotensinogen to angiotensin I
- Angiotensin II: vasoconstrictor; ↑ADH, aldosterone
- Renal conservation of fluid
  - ↓MAP → ↓RBF, GFR, and UO
  - ↑SY tone → afferent and efferent constriction → ↓RBF, GFR; ↑renin secretion (direct and via JGA)
  - ↑ATII → ↑Na reabsorption, arteriolar vasoconstriction
  - ↑aldosterone → ↑Na reabsorption from DCT + collecting ducts
  - ADH

**NB: timecourse:**

- seconds: baroreceptor, chemoreceptor, cerebral ischaemic response
- minutes: autoregulatory, angiotensin, ADH, capillary fluid shift
- hours: full effect of renal fluid retention

**Response to haemorrhage occurs in 3 phases with sig overlap**

- **hypovolaemia + cardiovascular compensation**
  - due to loss of circulating vol
  - no time for composition of intravascular fluid to change
  - osmoreceptors response: osmolality not yet changes → vaso released anyway by baroreceptors sensing loss of volume
  - baroreceptor response: ↓
    - VA tone → ↑SY tone → venous + arterial constriction → concentrating blood vol in central + cerebral circulation → ↑HR, ↑CO despite ↓preload
    - Can compensate for 10-15% loss and CO will not suffer very much
- **transcapillary fluid redistribution and isovolaemic anaemia**
  - restoration of blood vol by transcap refill → net movement of fluid + protein from interstitial compartment into intravascular compartment
  - SY: ↓diameter of arterioles → ↓pressure at capillaries
  - Oncotic pressure remains same; no longer balanced by high cap hydrostatic pressure → movement of free water out of the interstitial space and into the intravascular space → dilutes capillary fluid
  - Movement of interstitial albumin into intravascular compartment
- **renal fluid/ electrolyte conservation and haemopoiesis**
  - activation of RAAS → Na retention, Na<sup>+</sup> distributed into extracellular fluid
  - BM attempts to replenish lost RBC

**Figure 7-5.** Schematic diagram showing the increase in renin secretion and the increased production of angiotensin II in response to a major hemorrhage. Three primary mechanisms activate renin secretion: (1) increased renal sympathetic nerve activity; (2) decreased pressure sensed by intrarenal baroreceptors; and (3) decreased sodium chloride delivery to the macula densa. The first two mechanisms directly stimulate renin release, whereas the third mechanism reduces inhibitory feedback, allowing more renin release. Renin promotes the formation of angiotensin II, which produces strong vasoconstriction and helps to correct the decrease in blood pressure that resulted from the hemorrhage.

**Figure 7-7.** The macula densa NaCl load sensor. Macula densa cells in the thick ascending limb sense sodium chloride delivery by changing the uptake of salt with subsequent osmotic swelling (see Figure 7-3). Changes in cell volume lead to the release of chemical transmitters that alter renin secretion from the granular cells: When sodium chloride delivery increases, renin production decreases. GFR, glomerular filtration rate.

### Central neuraxial blockade: PAST QUESTION

- central neuraxial blockade achieved by: subarachnoid (spinal) or epidural
- LA (bupivacaine, ropivacaine) +/- opioid (fentanyl, morphine)
- Effects are more pronounced in:
  - o Elderly (↓physiological reserve)
  - o Fixed cardiac output states
  - o ↓blood volume

**response**

- ↓ MAP due to:
  - o blockade of alpha + beta SY chain fibres that innervate venous smooth muscle + control vasomotor tone
    - Run in thoracolumbar region (T5-T11) → level of block will affect degree of ↓MAP
    - MoA
      - Removes tonic SNS activity on vascular smooth muscle
      - Blocks α1 adrenoceptors (GPCR) → ↑PKC → ↑IP3/DAG → ↑Ca<sup>2+</sup> → constriction
      - Blocks β2 receptors (GPCR) → ↑cAMP → ↓Ca<sup>2+</sup> → dilation
    - Result
      - Vasodilation (arteriolar) → ↓afterload
      - Venodilation (venous) ↑capacitance → ↓VR → ↓CO
      - Veno effect >> arterial effect → 75% blood vol pools in venous circulation
- Level of block of SNS + effect of CVS response
  - o Sacral block: nil SY chain blockade (only PSY fibres) → minimal effect on peripheral vascular tone
  - o mid thoracic/ renal level → ↓GFR → activation fo RAAS by ↓afferent arteriolar stretch
  - o “high block”: T1-T4 cardio-accelerator centre → blockade → unable to ↑HR/contractility with SNS stimulation
  - o brainstem block: inhibition of vasomotor centre → unable to activate SNS response → profound ↓MAP

- **high pressure baroreceptors (carotid sinus + aortic arch)**
  - o sense:  $\downarrow$ stretch  $\rightarrow$   $\downarrow$ inhibitory input to SNS  $\rightarrow$  stimulation of vasomotor centre
  - o Result:
    - $\uparrow$ SNS:  $\uparrow$ HR,  $\uparrow$ contractility; vasoconstriction; venoconstriction
    - activation of RAAS:  $\uparrow$ renin; ATII: direct vasoconstriction;  $\uparrow$ ADH;  $\uparrow$ H<sub>2</sub>O reabsorption from DVT
- **Low pressure baroreceptors (RA, great vessels)**
  - o Sense:  $\downarrow$ stretch  $\rightarrow$   $\downarrow$ ANP secretion
  - o Result:
    - $\downarrow$ inhibition RAA/ ADH system:  $\downarrow$ Na/H<sub>2</sub>O releas

### Cardiovascular changes that occur with ageing

*Heart*

- Muscle
  - o ↓number of myocytes; LVH + ↑cardiac mass
  - o ↑collagen + fibrous tissue deposition → impair compliance + early LV diastolic filling

- LV relaxation less efficient in diastole → ↓compliance
- Atrial contraction more important to ventricular filling contributing ~40% LVEDV (AF can lead to significant ↓CO)
- Innervation
  - Downregulation of B adrenoceptors
    - ↓affinity + alteration in signal transduction
    - attenuated Breceptor responses → ↓max HR + ↓peak EF → ↑susceptibility to cardiac failure
    - ↑SNS activity → ↑plasma catecholamine concentration
- Electrical
  - Calcific + fibrotic degeneration of conducting pathways + fatty infiltration of pacemaker cells
    - AF common; SSS
    - ↓intrinsic sinus rate but overall HR preserved by ↑SY tone
    - ↓max HR

**Vessels**

- calcification + intimal thickening + breakdown of elastin
  - ↓compliance
  - widened pulse pressure
  - loss of elastin in prox thoracic aorta + prox branches of greater vessels → progressive central aortic dilation
- Degeneration of coronary vessels
  - Atherosclerotic change -- ↓calibre of coronary vessels → ↑CVR + ↓CorBF
- Baroreceptors
  - ↓sensitivity: ↓reflex adaptations to hypotension → more labile BP
- Calcification of aorta
  - ↓compliance → ↑afterload → LVH → ↓compliance
  - ↑SBP ↑DBP
  - ↑aortic stiffness resulting in ↑pulse wave velocity
  - ↓time between systole + diastolic peak pressures

*Cardiovascular changes that occur with morbid obesity***Obesity**

- excessive fat accumulation in adipose tissue
- WHO classification based on BMI (weight in kg/ height in m<sup>2</sup>)

**Changes in CVS**

- depend on extent + duration of obesity
- extra adipose tissue needs ↑CO
  - ↑SNS
    - ↑HR + ↑SV
    - ↑RAAS → Na<sup>+</sup> retention → ↑blood vol → ↑MAP
    - ↑MAP → LVH → LV dilation → LV failure
- OSA
  - Pulmonary HTN → cor pulmonale
  - Polycythaemia → ↑viscosity
- Compression of abdominal + leg vessels
  - ↓VR → supine hypotension + ↑risk DVTs
- insulin resistance + hyperlipidaemia → inflammatory mediator upregulation → disrupt endothelial function → IHD + cerebrovascular disease + PVD
- direct deposition of fat in myocardium → conduction disease + cardiomyopathy

**CVS diseases associated with obesity:**

- associated with HTN, HF, IHD, cardiomyopathy, sudden cardiac death, arrhythmias, PVD, DVT, CVD

*List the physiological factors that affect left atrial pressure (LAP) and explain their effects. Draw LA pulse trace I. time: PAST QUESTION*

- LA: receives all of CO returning from pulmonary circulation
- Pulmonary circulation = low pressure (0-25mmHg)
- Normal LAP = 0-8mmHg

**LAP trace**

- **a wave:** atrial contraction
- **c wave:** ventricular contraction → bulging of mitral valve into LA
- **x descent:** pressure ↓ 2° shortening of ventricles → atria pulled → ↑atrial capacity with ↓pressure
- **v wave:** atrial filling against closed MV
- **y descent:** passive ventricular filling after opening of mitral valve

**Factors affecting LAP**

- **LA filling**
  - Blood vol passes through pulmonary circulation + drains into LA via pulmonary vein
  - Influenced by:
    - Blood vol: ↑filling → ↑LAP
    - Posture: upright → ↓VR → ↓LAP; supine → ↑VR → ↑LAP
    - Pulmonary venous tone: ↑tone → vasoconstriction → ↑VR → ↑LAP
    - ITP:
      - ↑pressure (expiration/ IPPV/ PEEP) → ↓VR → ↓LAP
      - ↓pressure (inspiration) → ↑VR → ↑LAP
- **LA emptying/ ventricular filling**
  - Passive + active (atrial kick)
  - AV ring size: ↓outlet through AV ring → ↑resistance → ↑LAP
  - Mitral valve incompetence: regurgitation of blood → ↑LA volume → ↑LAP
  - Atrial contraction: absence of contraction: ↑LAP
- **Ventricular emptying**
  - Aortic valve incompetence: inadequate closure at end-systole → regurg of blood → ↑ES LV vol → ↑diastolic filling pressure → ↑LAP

- (e.g. aortic stenosis/ sclerosis)
- LV contractility:  $\downarrow$ LV function  $\rightarrow \uparrow$ LVESV  $\rightarrow \uparrow$ diastolic filling pressure  $\rightarrow \uparrow$ LAP (e.g. lateral MI, LVF)
- Aortic valve outlet size:  $\downarrow$ LV outlet size  $\rightarrow \uparrow$ LV pressure  $\rightarrow \uparrow$ LAP (e.g. aortic stenosis/ sclerosis)
- IPPV:  $\downarrow$ wall tension  $\rightarrow \downarrow$ afterload

*Describe the pathways whereby myocardial ischaemia may be experienced as pain in the throat or arm regions: PAST QUESTION*

- pain: unpleasant sensory + emotional experience associated with actual or potential tissue damage or described in terms of such damage
- referred pain: pain perceived as coming from an area or situation remote from its actual origin

#### **Supply vs. demand**

- inadequate supply of blood to supply the O<sub>2</sub> required for the metabolic demands of the heart
- heart = dependent on aerobic metabolism
- metabolic demands (vol of O<sub>2</sub> consumed) by heart = determined by amount + type of activity of the myocardium (stroke work)
  - stroke work = SV x afterload
    - Afterload: pressure against which the blood is ejected by LV
    - SV determined by: preload, afterload, contractility
  - Myocardial O<sub>2</sub> ER ~70% = nearly maximal under basal conditions  $\rightarrow$  O<sub>2</sub> supply is dependent on CBF (flow limited)
  - $\uparrow$ HR,  $\uparrow$ afterload,  $\uparrow$ contractility  $\rightarrow \uparrow$ O<sub>2</sub> requirement  $\rightarrow$  ischaemia if CorBF does not  $\uparrow$  to meet demands

#### **Myocardial ischaemia**

- ischaemia  $\rightarrow \downarrow$ ATP formation  $\rightarrow$  accumulation of metabolic products that stimulate pain endings in the myocardium  $\rightarrow \downarrow$ pH,  $\uparrow$ lactate, serotonin, bradykinin, histamine, O<sub>2</sub> species, adenosine
- **adenosine** = primary mediator of angina: stimulates A<sub>1</sub> adenosine R GPCR  $\rightarrow$  Gi  $\rightarrow$  adenylyl cyclase inhibition  $\rightarrow \downarrow$ intracellular cAMP
- c fibres travel along SY afferent pathways from heart  $\rightarrow$  enter SC through superior thoracic ganglia of SY trunk

#### **Myocardial ischaemia as referred pain**

- type of referred pain: i.e. irritation of visceral organ  $\rightarrow$  produces pain in somatic structure that may be distance away
- pain of myocardial ischaemia or infarction commonly radiates from substernal region + L pectoral region to shoulder/ L arm/ throat
- **convergence-projection theory**
  - convergence of somatic + viscereal pain fibres on same 2<sup>nd</sup> order neuron in dorsal horn that project to thalamus  $\rightarrow$  somatosensory cortex
  - axons of 1<sup>o</sup> sensory neurons enter spinal cord segments C7-T4
  - end point: cardiac pain follows dermatomal rule: heart developed at same embryonic segmental origin as the arm  $\rightarrow$  therefore is referred to the L side of the chest + medial aspect of the arm

*Explain how O<sub>2</sub> supply of organs is maintained during isovolaemic haemodilution: PAST QUESTION***Isovolaemic haemodilution**

- replacement of a portion of blood vol with fluid which doesn't possess O<sub>2</sub> carrying capacity e.g. NS/CSL → therefore nil effect on circulating vol
- Effect:
  - ↓concentration of blood components + ↓[Hb]
  - O<sub>2</sub> content in blood determined by:
    - $\text{CaO}_2 = \text{O}_2 \text{ bound in blood} + \text{dissolved O}_2$
    - $\text{CaO}_2 \text{ mg/L} = ([\text{Hb}] \times \text{SaO}_2 \times 1.34) + (\text{PaO}_2 \times 0.003)$
    - 99% O<sub>2</sub> bound to Hb; 1% dissolved in solution → therefore ↓[Hb] → ↓O<sub>2</sub> carrying capacity of blood
  - O<sub>2</sub> flux equation describes delivery of O<sub>2</sub> to organs
    - $\text{DO}_2 = \text{CaO}_2 \times \text{CO}$
    - Therefore during isovolaemic haemodilution, O<sub>2</sub> supply can be maintained by changes to CO

**Maintenance of O<sub>2</sub> supply**

- **changes to CO**
  - CO directly proportional to [Hb]
  - O<sub>2</sub> supply usually maintained by ↑CO (CO = HR x SV)
  - Viscosity
    - Isovolaemic haemodilution → ↓viscosity due to loss of blood components
    - According to Hagen-Poiseuille:  $\text{flow} = \pi r^4 / 8\eta L$  → ↓viscosity → ↑flow
    - ↓viscosity → ↑CO
      - Via Frank-Starling reflex: ↓viscosity → ↑VR → ↑SV → ↑CO
      - ↓viscosity → ↓SVR and ↓afterload → ↑CO
  - SNS stimulation
    - Metabolic organ blood flow autoregulation: ↓PO<sub>2</sub> → ↑lactate/ H<sup>+</sup> and ↓pH → ↓TPR
    - ↓TPR → ↓MAP → high pressure baroreceptors → ↑SNS stimulation → ↑preload 2o venoconstriction → ↑VR, ↑HR, ↑SV/contractility
- **improved O<sub>2</sub> ER**
  - Fick:  $\text{VO}_2 = Q(\text{CaO}_2 - \text{CvO}_2)$ 
    - Where: CaO<sub>2</sub> = arterial O<sub>2</sub> content; CvO<sub>2</sub> = venous O<sub>2</sub> content; Q = CO
    - Therefore ↑O<sub>2</sub>ER can occur with ↓CvO<sub>2</sub>
  - Bohr effect
- **Redistribution of blood to vital organs**
- **↑EPO production**

## CARDIOVASCULAR PHARMACOLOGY

Describe the autonomic nervous system and its physiological roles including: • Autonomic receptors and cellular effects of receptor activation • Autonomic transmitters, their synthesis, release and fate

- Subdivided into central ANS + peripheral ANS
- regulates visceral functions + involuntary control → haemodynamics (CO, SVR), respiration, GI, urination + defecation, thermoregulation, sexual function

### 1. Central ANS

- Hypothalamus, brainstem, spinal cord
- Neural + endocrine role
- tonic output to: smooth muscle, heart, exocrine/ endocrine organs, GIT, GU
- 4 regions:
  - o 1. Anterior hypothalamus: supraoptic + paraventricular nuclei → controls PSY, heat loss, ADH + oxytocin
  - o 2. Medial hypothalamus: ventro + dorsomedial n. → energy + sexual behaviour
  - o 3. Lateral hypothalamus: emotions, thirst, food
  - o 4. Posterior hypothalamus: SY outflow; vasomotor centres

### 2. Peripheral ANS

- Divided into: SY + PSY. Differ in: length of neurons, location of ganglia (synapses), and NT

| Feature                                             | Division of ANS                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

### Enteric plexus

- autonomic nerves in GIT free of CNS control
- sensory + integrative neurons + excitatory + inhibitory motor neurons
- excitatory interneurons + motor neurons release ACh as NT
- other interneurons release serotonin, vasoactive intestinal peptide, NO

**Figure 56.1** Layout of the ANS.

### Neurotransmitters and receptors in general

#### Neurotransmitters

- Substance released by a neuron at a synapse → affects post-synaptic cell
- NT release
  - o NT stored in vesicles on pre-synaptic membrane
  - o AP into terminal bouton: N-type voltage gated  $\text{Ca}^{2+}$  channels open → ↑presynaptic  $[\text{Ca}^{2+}]$
  - o Exocytosis:  $\text{Ca}^{2+}$  binds to vesicular membrane protein (synaptotagmin) + SNAREs → trigger vesicle fusion with pre-synaptic membrane
  - o Diffusion across synaptic cleft down conc gradient
  - o Binding to post-synaptic Rs → excitation / inhibition
- **Classified as:**
  1. **Amino acids:** Glutamate; GABA; Glycine
  2. **Monoamines:** ACh; Serotonin; Histamine
  3. **Catecholamines:** Dopamine; Noradrenaline; Adrenaline
- Termination of neurotransmission
  - o NT removed from synaptic cleft via diffusion or degradation
  - o Neuronal reuptake: active transport back into presynaptic membrane eg NA, dopamine

#### Receptors

1. **Inotropic**
  - o Ligand gated post-synaptic ion channels e.g. GABA, NMDA
  - o EPSP or IPSP
    - EPSP: NT binding at post-synaptic membrane opens non-specific cation channels → N intracellular movement of +vely charged ions → depolarisation
    - IPSP: ligand gated  $\text{K}^+$  or  $\text{Cl}^-$  channels on post synaptic membrane
      - $\text{K}^+$  mediated:  $\text{K}^+$  down EC gradient out of cell → efflux +vely charged ions -
      - $\text{Cl}^-$  mediated: intracellular movement of  $\text{Cl}^-$  → ↑difficulty depolarising cell membrane = "chloride damp"
2. **Metabotropic**
  - o effects via chemical 2<sup>nd</sup> messengers e.g. muscarinic ACh
  - o NT binds → conformational change → GPCR (no ion channel opening)

*Neurotransmitters in the ANS***Neurotransmitters in the ANS**

2 main NT:

**1. ACh**

- Role
  - Preganglionic NT in SY + PSY
  - Postganglionic NT in PSY
  - Adrenal medulla pre-ganglionic neurons → ACh
  - Sweat glands: post ganglionic fibres release ACh
- **Receptors:**
  - **Nicotinic**
    - ligand gated; at NMJ
    - large protein; 5 subunits ( $\alpha 1$ ,  $\alpha 2$ ,  $\beta$ ,  $\gamma$ ,  $\delta$ )
    - ACh binds to  $\alpha$  chains → conformational change → opens ion channel → inward Na + outward K
    - Agonist = nicotine / Antagonist = curare
  - **Muscarinic**
    - GPCR (metabotropic); in heart → activates PLC, inhibits AC, or opens K ion channels
    - **5 subtypes**
      - **M1:** CNS, autonomic ganglia, gastric parietal cells → ↑ intracellular IP<sub>3</sub> + DAG → ↓ K conductance + ↓ depol
      - **M2:** atrial + conducting tissue of heart → ↓ intracellular cAMP → ↑ K conductance → inhibitory
      - **M3:** glandular secretion + visceral SM contraction 2° ↑ IP<sub>3</sub>
      - **M4 + M5:** CNS

**2. Noradrenaline**

- Released at **postganglionic** nerve endings of **SYNS** → excitatory (vasoconstriction) + inhibitory effects
- Located in: locus ceruleus, medullary + pontine nuclei
- Synthesis: dopamine → converted to NA by dopamine-hydroxylase in neurons + adrenal medulla
- Fate: metabolised to inactive compounds by MAO (oxidation) and COMT (methylation)
- Adrenergic receptors (adrenoceptors) = GPCR; 4 main subtypes

|            | Type  | Location                                             | Action                                                                                                                                                                                                       | Agonist                             | Antagonist |

Neuromodulators:

**3. Peptides:**

- E.g.: enkephalin, neuropeptide Y, vasoactive intestinal peptide, neurotensin
- Modulate synaptic excitability: ↑ or ↓ efficacy of synaptic transmission without acting directly as NTs = “neuromodulation”

**4. Other chemical mediators**

- Prostaglandins
- Adenosine
- Dopamine
- Serotonin
- GABA

*Outline the main biochemical events involved in noradrenergic transmission. Outline how these may be altered by the use of monoamine oxidase inhibitors: PAST QUESTION*

- post synaptic SY nerve fibres (except SY innervation of sweat glands + sl
- CNS pathways governing mood / pain

#### NAd synthesis

- Occurs in axoplasm of terminal nerve endings
- **phenylalanine** → phenylalanine hydroxylase in liver → **tyrosine** → tyro cytoplasm → **dopamine** → dopamine β-hydroxylase in cytoplasm → **NAd**

#### NAd storage + release

- stored in vesicles in nerve terminal of post-ganglionic fibres
- AP arrives: open voltage gated Ca<sup>2+</sup> channels → Ca<sup>2+</sup> influx → Ca<sup>2+</sup> d

#### Interaction of NAd + receptor

- **NAd acts of presynaptic adrenergic Rs**
  - o α<sub>2</sub> adrenergic R: Gi → ↓AC → ↓[cAMP] → ↓PKA → ↓[Ca<sup>2+</sup> modulate own release from presynaptic terminal
- **NAd acts on post-synaptic adrenergic Rs**
  - o α<sub>1</sub> adrenergic R: Gq → IP<sub>3</sub>/ DAG → downstream effects
  - o β<sub>1</sub> R: Gs → ↑AC → ↑[cAMP] → ↑PKA → downstream effects
  - o β<sub>2</sub> R: Gs → ↑AC → ↑[cAMP] → ↑PKA → downstream effects

#### Metabolism + reuptake

- NAd in synaptic cleft →
  - o Uptake 1 (major pathway): reuptake into pre-synaptic terminal → oxidative deamination by MAOA → metabolites resynthesised into NAd or elimination from synapse + excreted in urine
  - o Uptake 2 (minor pathway): diffusion away from synaptic cleft → methylation by COMT (not found in SY nerve terminals)
- Terminal metabolites: VMA + MHPG → excreted in urine

#### MAOI

- 2 types of MAO located on outer mitochondrial membrane
  - o MAO-A deaminates NAd, Ad, 5HT
  - o MAO-B deaminates tyramine + 2-phenylethylamine
- Therefore inhibition of MAO-A → ↓metabolism of NAd, Ad, 5HT → ↑availability and action → ↑SNS activity, CNS excitation
- MAOI may interact with other meds: e.g.
  - o Sympathomimetics: prolong action → ↑SNS
  - o SSRI: precipitate serotonin syndrome
  - o Tyramine rich foods e.g. cheese → catecholamine release → HTN crisis
- MAO inhibitors
  - o Non selective MAOI: phenelzine
  - o Selective MAO-A inhibitor: moclobemide
  - o Selective MAO-B inhibitor: selegiline

### Describe the mechanism of action and effects of sympathomimetic and anticholinergic drugs used clinically

| Sympathomimetic drugs                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Anticholinergics                                                                                                                                                                                                                  |

#### Structure activity relationship of sympathomimetics: MAKEUP

- Catecholamine
  - o Cetechol + ethylamine
    - Catechol: benzene ring; -OH groups on C3 and C4
    - Ethylamine: α and β carbons + terminal -NH<sub>2</sub>
- Metabolism
  - o Catecholamines: 3,4-di-hydroxy-benzene structures → metabolised by MAO + COMT (COMT requires both -OH groups on C3 and C4)
  - o Synthetic non-catecholamines: lack of -OH group on C4; emtabolised only by MAO → slower
- Direct vs. indirect activity
  - o Direct activity: OH group on C3; OH group on βC
  - o Indirect activity: ephedrine
- Receptor selectivity

- Adrenaline
  - Ultimate catecholamine
  - Any change in chemical structure → change in  $\alpha$  +/-  $\beta$  activity
- Norad:
  - Lack of -CH<sub>3</sub> group on terminal amine → catecholamine (OH group on C3 and C4); direct activity (OH group on C3 and  $\beta$ C); mainly  $\alpha$ 1 activity; some  $\beta$  activity
- Phenylephrine
  - Lack of OH group on C4 → non catecholamine; direct activity; ↑ $\alpha$ 1 activity; no  $\beta$  activity
- Isoprenaline
  - Isopropyl group on terminal amine → catecholamine; direct activity;  $\beta$  activity; no  $\alpha$  activity

### Describe the pharmacology and clinical application of adrenergic agonists

| Adrenergic / sympathomimetic drugs:                                                                                                                                                                                             | Non-adrenergic drugs                                                                                                                                                  |

*Describe the mechanism of action of inotropes and provide examples: PAST QUESTION*

Inotropes = drugs that ↑cardiac contractility (i.e. ↑SV for given preload + afterload)

Cardiac contractility

- main determinant = intracellular  $[Ca^{2+}]$
- ↑cAMP → ↑intracellular  $[Ca^{2+}]$  → ↑inotropy

Myocardial excitation contraction coupling:

- AP reaches cardiac myocyte
- $Ca^{2+}$  moves down conc gradient → influx mainly via L-type  $Ca^{2+}$  channels
- $Ca^{2+}$  induced  $Ca^{2+}$  release from SR via RYR
- ↑↑intracellular  $[Ca^{2+}]$  from 0.1  $\mu M$  to 10  $\mu M$
- $Ca^{2+}$  binds troponin C → actin myosin interaction → contraction

$\beta_1$  adrenoceptors = GPCR → coupled to  $G_s$  → activation stimulates AC → ↑cAMP → ↑PKA →

- phosphorylates + activates L type  $Ca^{2+}$  channels → ↑ $Ca^{2+}$  entry
- phosphorylates + activates sites on SR → ↑RyR release of  $Ca^{2+}$  → ↑CICR

*Inotropes*

- $\beta$  blockers competitively antagonist  $\beta$  adrenoceptor activation by endogenous Ad + NAd
- Divided into:
  - o  $\beta_1$  selective: e.g. esmolol, bisoprolol, atenolol, metoprolol
  - o non selective  $\beta$  blockade e.g. propranolol
  - o non selective  $\alpha + \beta$  blockade e.g. labetalol, carbetilol
  - o others: e.g. sotalol (also acts on K channels as class III antiarrhythmic)

- Therapeutic uses

| Clinical use         | Mechanism                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## Outline clinically important drug interactions with the autonomic nervous system

### Physiological and pharmacological basis of antiarrhythmic therapy including classification based on electro-physiological activity and mechanism of action

#### Physiological

- heart composed of pacemaker, conducting, contractile tissue
- SA node:
  - o in RA; fastest rate of spont depolarisation → sets HR
  - o slow spont depol due to ↑Ca<sup>2+</sup> conductance
  - o at -40mV, slow voltage gated Ca<sup>2+</sup> channels (L channels) open → membrane depolarisation
  - o repolarisation due to ↑K<sup>+</sup> conductance + closing Ca<sup>2+</sup> channels
- Cardiac muscle
  - o Stable RMP -80mV
  - o Phase 0: rapid repolarisation 2o ↑Na<sup>+</sup> conductance through voltage gated Na<sup>+</sup> channels
  - o Phase 1: closure of Na<sup>+</sup> channels
  - o Plateau phase: Ca<sup>2+</sup> influx via voltage sensitive L type Ca<sup>2+</sup> channels; absolute refractory period (prevents myocardial tetany)
  - o Phase 3: Ca<sup>2+</sup> channels inactivated; ↑K<sup>+</sup> conductance; relative refractory period
  - o Phase 4: Na/K/ATPase maintains ionic concentration gradient
- Tachyarrhythmias
  - o ↑automaticity where RMP of contractile tissue loses stability → reaches threshold for depolarisation prior to SA node (e.g. ischaemia + hypokalaemia)
- Bradyarrhythmias
  - o Due to failure of conduction from SA node to surrounding tissue

#### Pharmacological

- **Classification based on electro-physiological activity - Vaughan-Williams classification**

| Class | Mechanism                                                                                                                                                                                                  | Site of action                            | Drugs                               |

- o NB: VW classification does not include all drugs + individual agents fall into multiple categories

- **Classification based on clinical use:**

- o SVT: digoxin / adenosine / verapamil / βblockers / quinidine
- o VT: lignocaine
- o SVT + VT: amiodarone / flecainide / procainamide / sotalol

Describe the pharmacology of antiarrhythmic agents and their clinical applications including the following agents: lignocaine, flecainide, beta blockers, amiodarone, sotalol, ibutilide, calcium antagonists, digoxin, adenosine and magnesium

#### Antiarrhythmics (from CICM)

- Sodium channel blockers
  - o Procainamide (B)
  - o Lignocaine (A)
  - o Flecainide (B)
- Beta blockers (A) – See section on B blockers
  - o Sotalol (A) – See section on B blockers
- Potassium channel blockers
  - o Amiodarone
  - o Sotalol
- Calcium channel blockers (A)

- non-dihydropyridines:
  - phenyl alkamines: verapamil
  - benzothiazepines: diltiazem
- dihydropyridines: nimodipine, nifedipine, amlodipine
- Other
  - Amiodarone,
  - Digoxin (A)
  - Adenosine (A)
  - Magnesium (A)

*NB on CCB:*

- caution when using with BB
- ↑serum concentration of dig
- NB volatiles ↓Ca<sup>2+</sup> release from SR and ↓Ca<sup>2+</sup> flux inot cardiac cells: -ve inotropic effects are additive
- ↓MAC
- ↑efficacy of NMB

*Sodium channel blockers*

*Management of hypertensive crisis: PAST QUESTION*

Hypertensive crisis = severe HTN + acute end organ impairment

- may be associated with: APO, MI, arterial dissection, eclampsia, SY crisis, cocaine OD, renal failure

**Classification of antihypertensives based on site of action**

- **Vasodilators**
  - o **Direct arteriolar dilators**
    - **Hydralazine**: activates guanylate cyclase → ↓Ca<sup>2+</sup> release + entry into cells, electromechanical decoupling → smooth muscle relaxation; arterial > venous; onset 10mins; duration 3-6hrs
    - **Minoxidil**: ↑K into vascular smooth muscle → hyperpolarization → ↓smooth muscle contraction + vasodilation
    - **Diazoxide**: K channel activator → ↓Ca<sup>2+</sup> into cell → smooth muscle relaxation
  - o **NO stimulators**
    - **Sodium nitroprusside**: direct acting, non selective vasodilator. Interacts with oxyhb → dissociates → metHb + released CN + NO → NO activates guanylate cyclase → ↑cGMP → ↓Ca<sup>2+</sup> entry → vasodilation
    - **GTN**: generates NO → ↑cGMP activation → dilation
  - o **CCB**
    - **Nicardipine**: dihydropyridine CCB; prevents Ca<sup>2+</sup> entry into vascular smooth muscle by allosteric modulation of L type VG Ca<sup>2+</sup> channels. Onset: 10mins; duration 4-6hrs
- **Sympatholytics**
  - o **BBlockers**
    - **Esmolol**: cardioselective β1 antagonist; antagonizes effects of ADR + NAD at β1 ; ultra short acting
  - o **a+B adrenergic blockers**
    - **labetalol**: α1, β1, β2 antagonist; ↓SVR; onset 2-5mins; peak 10mins; lasts 3hr
  - o **a-blockers**
    - **prazosine**: selective post synaptic α1 antagonist → ven + art vasodilation
    - **phentolamine**: α1:α2 5:1 → ↓SVR
  - o **centrally acting blockers**
    - **methyldopa**: metabolised to a-methyl NOad → α2 agonist at presynaptic terminals → ↓SNS discharge
    - **clonidine**: centrally acting α2 agonist → ↓SNS output
- **inhibition of RAAS**
  - o (less likely to be used in crisis due to difficulty titrating)
  - o **ACEI**: blocks conversion of ATI → ATII → ↓vasoconstriction, ↓aldosterone, ↓SNS activation, ↓Na + H<sub>2</sub>O retention
  - o **ATII**: blocks vasoconstrictive effects of ATII
- **anaesthetic agents** with hypotensive SE
  - o **volatile anaesthetics**
  - o **opioids** e.g. morphine: histamine release + ↓SY tone
  - o **Propofol**: vascular smooth muscle relaxation; inhibition of SY vasoconstrictor nerve activity; -ve inotrope
  - o **LA**: neuraxial blockade → dilation of vessels

*Describe the mechanism and treatment of the toxicity of sodium nitroprusside: PAST QUESTION*

SNP = mixed vasodilator + venodilator

**Structure + metabolism of SNP**

- MoA:
  - o Structure: Na<sub>2</sub>[Fe<sup>III</sup>(CN)<sub>5</sub>(NO)]
  - o Prodrug; exerts action via release of NO
  - o SNP oxidises Hb in RBC to MetHb → dissociates into Fe<sup>3+</sup> + 5CN + NO
  - o NO activates soluble GC → ↑cGMP → protein kinase G → ↓intracellular [Ca<sup>2+</sup>] → inhibit MLCK activity → smooth muscle relaxation → vaso + veno dilation)
- Metabolism
  - o Results in: CN, NO, Fe<sup>3+</sup>, MetHb
  - o CN further metabolised in 3 ways:
    1. MetHb + CN → cyanomethaemoglobin (non-toxic)
    2. VitB12 + CN → cyanocobalamin (renal excretion)
    3. thiosulfate + CN → catalysed by hepatic rhodanese → thiocyanate (renal excretion)

**Toxicity**

- warning signs: ↑venous PO<sub>2</sub>, metabolic acidosis, tachyphylaxis

| Product                  | Toxicity                                                                                                                                                                                                                                                                                             | Treatment                                                                                                                                                                                                                                                                                                                  |

## Describe the pharmacology of drugs used to manage myocardial ischaemia/infarction, including: nitrates, beta blockers, calcium antagonists, anti-platelet agents, anticoagulants and fibrinolytic agents

Myocardial ischaemia results from inadequate circulation of blood to the myocardium

- rx aims to improve ratio between O<sub>2</sub> supply + demand
- Myocardial O<sub>2</sub> demand determined by:
  - o HR: ↑chronotropy → ↑demand
  - o Contractility: ↑inotropy → ↑demand
  - o Myocardial wall tension: ↑wall tension → ↑demand
- Myocardial O<sub>2</sub> supply determined by:
  - o CorBF
  - o MAP
  - o HR: ↑HR → ↓diastolic filling time → ↓supply (esp. LV)

Primary effects = ↓HR + ↓contractility → ↑diastolic filling time + ↓O<sub>2</sub> demand → ↑supply

NB the clinical effects + potential for adverse effects are synergistic with each of these + other agents

## Describe the pharmacology of drugs used to manage acute or chronic cardiac failure, including: sympathomimetics, phosphodiesterase inhibitors, digoxin, diuretics, ACE inhibitors, nitrates and beta blockers

### Classes of drugs used clinically to treat chronic LVF (past question)

- LV unable to provide sufficient pump action to distribute blood flow to meet metabolic demand of systemic circulation; or can only do so from elevated filling pressures (i.e. ↑CVP)
- Classification
  1. LV **systolic failure**: impaired LV **contractility**
  2. LV **diastolic failure**: impaired LV **filling**
  3. Mixed LV **systolic** + **diastolic failure**
- Compensatory mechanisms:
  4. ↑preload (via ↑RAAS, ↑ADH → fluid retention)
  5. ↑SY tone → ↑contractility
  6. over time, compensatory mechanisms fail → worsen LV failure
- Clinical features:
  7. Pulmonary congestion (SOB, orthopnoea, PND, ↓ET, fatigue)
  8. Functional classification based on NYHA
    - Class I: no limitation
    - Class II: mild limitation of activity; comfortable at rest/ minimal exertion
    - Class III: marked limitation of activity; only comfortable at rest
    - Class IV: symptoms at rest

Drugs used in HF

- **Systolic + diastolic HF**
  1. ACEI
    - ↓afterload / ↓preload

- Blocks conversion of ATI to ATII
- ↓vasoconstriction + aldosterone release + ↓SVR + ↓Na + H<sub>2</sub>O retention + ↓LV remodeling
- 2. **ATII R blockers**
  - Competitive inhibition of ATII at AT1 R
  - Effects as for ACEI
- 3. **B blockers**
  - B1 selective (metoprolol, bisoprolol, carvedilol) → competitive antagonist of Adr and NAd at B1 R
  - *Cardiac:*
    - ↓activation of adenylate cyclase → ↓cAMP → ↓Ca<sup>2+</sup> release → -ve inotrope/ -ve chronotrope/ -ve dromotrope
    - ↓myocardial O<sub>2</sub> demand
    - ↑diastolic perfusion time
    - ↑O<sub>2</sub> supply
  - *Renal*
    - ↓renin release from JGA → ↓ATII → ↓preload/ afterload
  - *Mortality:*
    - **Antiarrhythmic:** ↓chronotropy → ↑diastolic filling time
    - **Anti-ischaemic:** ↓chronotropy + ↓inotropy → ↓myocardial O<sub>2</sub> demand
    - **Attenuate catecholamine tox** → ↓renin → ↓RASS
    - ↓LV remodeling
- 4. **Diuretics**
  - ↓intravascular vol → ↓preload → maintains failing LV at top part of Frank Starling curve → maximizes LV ejection
  - No survival benefit/ have symptomatic benefit
  - Loop diuretics: frusemide: inhibit Na/K/2Cl reabsorption in TAL LoH → Na+ H<sub>2</sub>O excretion, vasodilation → ↓SVR
  - Aldosterone/ K sparing (spironolactone): competitive antagonism of aldosterone Rs → ↓basolat Na/K pumps in DT + CD → ↓Na, H<sub>2</sub>O retention while preserving K<sup>+</sup> → ↓preload
  - Thiazides : ↓Na/H<sub>2</sub>O reabsorption in DCT
- **Systolic only**
  1. **Digoxin:**
    - **↑contractility:** inhibits Na/K ATPase → ↑Na<sup>+</sup> + ↑Ca<sup>2+</sup> → ↑contractility
    - direct ↑VA cardiac activity → ↓conduction at AV node → ↓HR → ↑diastolic filling time → rate control in AF
    - nil improvement in mortality; improvement in morbidity
  2. **Nitrates:**
    - **↓preload / ↓afterload:**
    - NO activates guanylate cyclase → ↑cGMP → ↓cytoplasmic Ca<sup>2+</sup> → venodilation, ↓preload
  3. **Hydralazine:**
    - **↓afterload / ↓preload**
    - ↑cGMP → ↓cytoplasmic Ca<sup>2+</sup> → venodilation → ↓afterload/ ↓preload
  4. **PDIII inhibitors:** (e.g. milrinone)
    - **↑contractility**
    - ↓breakdown cAMP → ↑contractility, ↓SVR
- **Diastolic only**
  1. **CCB:** competitive blockade of L-type Ca<sup>2+</sup> channel → ↓Ca<sup>2+</sup> in SA + AV node + contractile tissue → ↓chronotropy, ↓O<sub>2</sub> demand, ↑coronary artery dilation

### Diuretics

- drugs that act on the kidney to ↑UO
- clinically used in rx of:
  - o HTN
  - o Fluid overload in cardiac, renal, hepatic failure
  - o APO
  - o ↑ICP
